ANALYTICAL AND CONSULTING CHEMIST

THE CHEMICAL AND MICROSCOPICAL EXAMINATION OF COMMERCIAL PRODUCTS

PLEASE ADDRESS REPLY TO

OFFICE No 2 RECTOR ST. NEW YORK CITY
LABORATORY, MILBURN, NEW JERSEY

Andrew Wilson, Inc.,
Springfield, N.J.

January 4 th 1922.

Dear Sir:-

This is to certify that I have chemically analyzed and am familiar with the composition and properties of Wilson's O.K. Plant Spray, and have made extensive practical trials of the same covering a period of the past five years for such insects as Red Spider, Mealy Bug, Scale, Aphis and Grape Mildew, and have found the same uniformly efficient and entirely innocuous to the most tender plants. It had proven in my hands the most economical and efficient Plant Spray which I have ever used.

Very truly yours,

Dr. Edward C. Worden

Edward C. Worden, Ph.C., M.A., D.Sc., F.C.S. Member of the Chemical Societies of United States, England, France, Italy and Germany. Fellow of the Institute of France.

A MESSAGE

JUDGE J. T. MAREAN'S INCOMPARABLE DAHLIA CREATIONS
Produced By Himself in His Private Gardens at Green's Farms, Conn.

Introductions for 1922.—
ALL PRIZE WINNERS

HERCULES, decorative; quilled; enormous flower on strong straight stems; blending of tangerine and deep yellow. \$10.

JUDGE ALTON B. PARKER, decorative; fine golden buff; very large flower on strong stiff stem. \$10.

MABEL THATCHER, decorative; fine large pale yellow flower on strong stem. \$10.

MRS. JOSIAH T. MAREAN, peony flowered; perfect; extra large flower on strong wiry stem; beautiful old rose with golden shadings. \$15.

MRS. JOHN T. SCHEEPERS, decorative; very beautiful flower of a canary yellow changing to a soft pink suffusion on outer petals; strong stout stem. \$15.

OVER THERE, decorative; most attractive large flower on very strong stem; of a true self deep salmon color. \$10.

THE BASHFUL GIANT, decorative; the largest flower so far produced; strong stem, on which the flower turns its head slightly; fine apricot with golden shadings. \$10.

THE EMPEROR, decorative; unquestionably the most aristocratic of them all; a maroon of the finest type; very large flower, made up of long flat petals; a magnificent Prize Winner of the highest merit. \$25.

THE MERRY WIDOW, decorative; enormous blooms on stiff short stems, held erect; clear yellow, suffused with a pleasing shade of red but so arranged to make a handsomely colored Dahlia. \$10.

Introductions of 1921, all of which have "made good" and have taken Blue Ribbons at the Shows:

AGNES HAVILAND, decorative; fine rose-pink slightly suffused with yellow. Large flowers on strong stiff stem. \$6.00.

CHARM, decorative; burnt orange shading to yellow; strong wiry stem. \$7.50.

DAKOTA, decorative; shade of flame; enormous flowers on stiff stem. \$6.

E. T. BEDFORD, Hybrid—decorative; purple with silvery shading; exhibited of size 12 inches and over. Long strong stems. \$10.

JUDGE MAREAN, decorative; blending shades of salmon pink, red, orange, yellow and pure gold; large flower on long strong straight stem. \$7.50.

LADY BETTY, decorative; lovely creamy-white, pinkish suffusion; very large, finely formed flower on stiff stem. \$7.50.

LA GROSSE BÊTE, decorative, enormous cerise self color; strong stem. \$7.50.

LE TORÉADOR, decorative; fine lasting exhibition flower; finest crimson shade; strong wiry stem. \$6.00.

MEPHISTOPHELES, Hybrid—decorative; a masterpiece; ruby red, tiny golden points at the very ends of some petals. Now \$15.

MRS. I. DE VER WARNER, decorative; considered the most beautiful in the collection; awarded many First Prizes at flower shows; very large beautifully colored flowers, a shade of soft deep mauve pink; long, strong, wiry stems. \$15.

STOCK OF ALL LIMITED

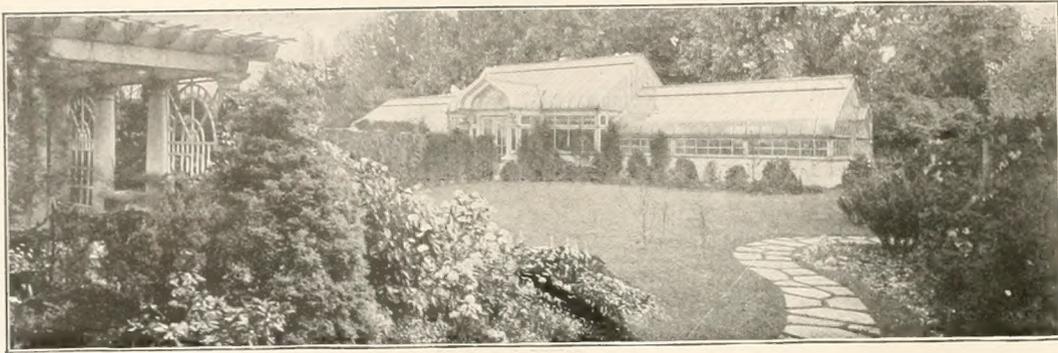

Prices are for **STRONG BULB DIVISIONS ONLY**; realizing what is often the result of propagation, **NO PLANTS** will be offered. **ONLY** Bulbs from clumps out of Judge Marean's private garden of which the plants **HAVE PROVEN THEIR MERIT**, will be distributed.

EACH VARIETY AND EACH ROOT SENT OUT IS ABSOLUTELY GUARANTEED AS TO BEING TRUE TO NAME AND TO PRODUCE A SATISFACTORY PLANT, BUT ONLY IF PURCHASED DIRECT FROM THE ORIGINATOR THROUGH HIS

OF INTEREST TO COUNTRY ESTATE OWNERS

The National Association of Gardeners takes this opportunity to place its Service Bureau at the disposal of owners of country estates when requiring competent gardeners, in the capacities of superintendents, head gardeners or assistant gardeners—thoroughly qualified in every particular to assume the responsibilities the positions call for—gardeners truly efficient in their profession.

The Bureau is maintained entirely at the expense of the association and makes no charge to the employer it may serve or to the member it may benefit.

NATIONAL ASSOCIATION OF GARDENERS

M. C. Ebel, Secretary

286 Fifth Ave.

New York

This association is in no sense a trade union organization, but includes in its sustaining membership owners of some of the foremost country estates in America.

Our Novelties for 1922

FOR approximately twenty years, we have been endeavoring to supply the best the world affords in flowers for your gardens. We leave it to you to judge, just how we have succeeded.

Our Catalogue for 1922, is Better than Ever!

Our new Rose "Souv. de Claudius Pernet," will prove itself the finest yellow Rose, distributed to date.

"Red Doty," and "Bronze Doty," are the finest introductions in this type, since the days of Lillian and White Doty!

Carnation "Happiness," the variegated yellow, is a Novelty in a class by itself.

And don't forget, "Royal Fragrance," Heliotrope!

These are just a few of the "gems" contained in our 1922 catalogue, which you should have received by this time. If your copy hasn't reached you—drop us a card!

Sutton's Seeds

The proverbial charm of English gardens is due to a great extent to the remarkable vigor of English seed and the purity of the strains. This outstanding superiority is present to a marked extent in American gardens when planted with Sutton's Seeds.

In England we raise the breeding of plants and the selection of seed to the dignity of an art. Superlative quality is our only standard: first in growing flowers and vegetables of unusual excellence, and finally in selecting seed from the perfect specimens only.

Our catalog, as unusual in its way as Sutton's Seeds, will be sent for 35c. This will be credited on first order of \$8.00 or over.

Only 28 days required from date of your order for catalog or seeds to reach you, as we mail promptly. But you should lose no time in ordering the catalog.

POPULAR Interest in Birds is shown in the increasingly definite movement to protect and to concentrate them where they are especially desired. Not only those who need their help in fighting insect pests, but others who love to see and hear them, are eager to offer inducements in the way of nesting sites to invite their presence.

Educator Log Cabins

for Birds and Household Pets

\$10,000,000 is estimated as the annual loss to our forestry and timber interests caused by insects. In the stomach of a single Cedar Waxwing were found 100 canker worms, while a Scarlet Tanager has been seen to eat 630 gypsy moths inside of eighteen minutes. A Maryland Yellow-throat ate 3,500 plantlice in forty minutes.

Educator Products are Distinctive

Every Garden and Bird Lover will find our 32-page Booklet describing the complete line of Educator Log Cabins full of valuable hints how to attract birds and how to hold them. Show many Cabins "at work" under natural surroundings. A copy of this booklet is gladly sent free on request if you mention G. C.

JANUARY, 1922

No. 1

Things and Thoughts of the Garden

MONTAGUE FREE

IT IS, of course impossible to describe Kew in an article such as this, so the attempt will be made only to give the impression of a one-time Britisher, now an American, on returning to his Alma Mater after an absence of ten years.

One striking thing about Kew as viewed in 1921 is the marvellous recovery it has made since the setback due to the war. From pessimistic reports received during this period of its run down condition owing to lack of labor, coupled with the fact that onions were growing in the parterre in front of the palm house and the Palace lawn had been plowed for potatoes, one would be justified in thinking that years must elapse before it could regain its pre-war excellence. But apart from the poor appearance due entirely to the drought, Kew seemed to be looking exceptionally well and there were no evidences of neglect, but the drought certainly worked havoc with many of the plants, and it was interesting to notice their reaction to these dry conditions. The rhododendrons in the wilder section of the garden, where it was impossible to water them, were in a sorry condition. The bamboos, too, were showing signals of distress, but the hollies and holm oaks were apparently none the worse.

One of the important features of the garden and one that might be duplicated to advantage in many gardens, both public and private, was a large group planting made up entirely of trees and shrubs with various foliage. This, of course, is a feature that could easily be overdone and one in which it would be easy to get the wrong notes, unless the planter had perfect taste and good knowledge of the color and the texture of the material used.

A list of some of the plants used in this group may be of value and provide suggestions for anyone who may be sufficiently interested to try out a similar planting scheme. There were: *Prunus cerasifera atropurpurea* (*P. Pissardi*), the purple leaved plum; Japanese maples in variety; the evergreen *Euonymus Japonicus*, in both gold and silver variegated forms, (the type by the way, is hardy in Brooklyn in years when the winters are not too severe); *Cornus controversa variegata*, a large leaved species with white margins—probably not hardy in the north; *Cornus alba* var. *Spæthii*, leaves edged with yellow; *Artemisia tridentata* and *Santolina chamaecyparissus*, which provide a grey tint in the planting; *Catalpa bignonioides aurea*, a form with yellow leaves, very effective; *Berberis vulgaris* var. *atropurpurea*, the common purple leaved Barberry; *Acer Negundo variegata*, with silvery

variegation; *Acer Negundo aurea*, with yellow leaves; *Corylus maxima atropurpurea*, an extremely effective form with large leaves and the coloring of Copper Beech; *Diercilla florida variegata*; *Ligustrum ovalifolium variegatum*; *Ulmus campestris* var. *Louis van Houtte*, a form of the English Elm having its leaves tinged with yellow and many variegated varieties of *Ilex Aquifolium*.

* * *

The hot Summer and abundance of sunshine evidently proved satisfactory to aquatic plants in general and at Kew as at every other garden we visited, where aquatics were a feature, the water lilies were superb.

The formal water garden at Kew is indeed beautiful and possesses one or two unusual features. The central part is occupied by a long pool rounded at each end. This is used for the cultivation of hardy water lilies which are planted in baskets of suitable soil. On either side are two rectangular tanks which are filled with soil almost to their brims. In these such plants are grown as require wet soil but which do not need to be submerged. At each corner there are tanks, raised 2½ ft. or so above the level of the central pool and reaching to the height of the terrace which surrounds the water garden. Here may be seen a collection of miscellaneous aquatics, especially those kinds whose beauty is more apparent when subjected to the close inspection afforded by these raised tanks. On the terrace and serving to enclose the pools is a beautiful hedge of *Berberis stenophylla* which is kept sheared, but this apparently does not prevent it from blooming for it is reputed to be a wonderful sight in the Spring. It is a shrub that stands shearing well and forms such an admirable, impenetrable hedge that one regrets that it is not sufficient hardy to stand our climate. In the background one catches glimpses of an old red brick wall clothed with shrubs and climbers, and, back of this, trees of varied habit form an interesting skyline to which emphasis is given by the spire-like forms of one or two Lombardy Poplars.

An interesting pool in another part of the garden receives its water in the form of condensed steam from the pumping station. As a result of this the water never freezes over and it is possible to grow therein a number of plants which are usually looked upon as being tender. At the time of our visit, this pool was made gorgeous by water lilies of many hues; and its banks were attractive by reason of many plants of subtropical appearance such as *Thalia dealbata* and *Zizania aquatic*.

The Holly Walk, or Avenue, consists of a wonderfully complete collection of species and varieties of *Ilex*, including over seventy varieties of English holly, planted on either side of a walk extending a distance of eight hundred yards. This collection affords connoisseurs an admirable opportunity of studying the genus and the remarkable diversity of form which *Ilex aquifolium* exhibits. Probably in no other place would it be possible to find gathered together in one place so many distinct species and varieties. No fewer than ninety-seven are enumerated in the Kew "Handbook of Trees and Shrubs." The majority of these are, of course, evergreen. In addition to the specimens in the general collection there are many superb holly hedges and also many sheared specimens to be seen in the vicinity of the formal garden near the great palm house. Probably no evergreen is better adapted to withstand dry conditions than these noble plants, and it was not only at Kew that we noticed the ability of holly as a drought resistance tree. In Epping Forest, where most of the trees and shrubs were in a parlous condition, the holly was apparently no bit the worse for the unusual drought. It is also tolerant of shade, and many fine specimens were seen growing almost entirely overshadowed by large trees. What a pity English holly is not reliably hardy in our northern gardens!

The formal bedding at Kew is characterized by simplicity but at the same time it is rich and interesting. Carpet bedding is practically taboo. The onions had been dismissed from the parterre in front of the great palm house and it was gay with a variety of plants. The most conspicuous in this bright assemblage, strangely enough, were North American plants; and yet we seldom see them used as bedding plants in our own country.

The large central beds were occupied by tall growing pentstemons in light and dark red varieties and presented a truly magnificent appearance. The garden pentstemons have probably been derived from *P. cobaea* and *P. Hartwegii*. The former occur wild on the prairies from Kansas southwestward, and the latter is found in cool regions of Mexico. The garden forms that have been developed are a great improvement on the wild species and are extremely valuable for bedding purposes in climates that suit them. Why is it that they are not used in Eastern North America? Are our Summers too hot or is it too much trouble to carry them over the Winter as rooted cuttings? The other North American plant to be seen here was in the form of an exceptionally fine strain of *Phlox Drummondii*, a native of Texas. This makes an admirable bedding subject if plants are raised from seeds of a good strain and the long trailing growths pegged to the ground.

Other materials used in this series of beds were half-dwarf snapdragons in mixture,—a remarkably fine strain such as we seldom see in this country; the yellow *Calceolaria amplexicaulis*, still a favorite in almost all English bedding arrangements; and a double Marguerite that we assumed to be the variety "Mrs. Sander."

It is the practice at Kew to make up beds of some particular variety or other that may be new, or one that may be new, or one that may be old, so far as date of production or introduction is concerned, but whose merits as a plant for bedding purposes are unrecognized. For example there was an immense circular bed filled entirely with a dwarf, double-flowered, pink hollyhock, the name of which we have unfortunately lost. These plants, although well grown, were not more than three or four feet in height and were wonderfully effective. Then too, there was a lavender colored *Erigeron* which, when seen

massed in a bed about thirty feet by ten, was exceptionally good. We were unable to find a label on this plant, presumably someone had stolen it, but we assumed it to be the variety "Asa Gray."

When a garden contains something over 20,000 different species and varieties, as Kew does, it seems foolish to attempt to single out a few for special mention. And yet perhaps it may not be amiss to call attention to two or three that made a special impression on us.

Myoporum parvifolium seemed to possess great possibilities as a decorative plant. It is an evergreen trailer with abundant shoots thickly clothed with small bright green leaves. Its flowers are white, sweet scented, and freely produced. At Kew it was grown in hanging baskets about one foot in diameter and from these the shoots, covered with myriads of flowers, depended to a length of at least four feet, completely covering the baskets. It is not by any means a plant new to gardens, and yet it is seldom seen nowadays. Bailey's Cyclopaedia, in referring to this plant says: "In 1883 it was stated in the Garden that for 20 years many thousand plants of it had been sold annually in the flower markets of Paris. One grower always had a stock of 30,000 plants." It is a native of Australia and succeeds in a cool house.

A gigantic climbing honeysuckle *Lonicera Hildebrandtiana*, was diffusing its fragrance in the Temperate House. Its flowers, seven inches in length, are the largest known in the genus. They are variable in color, those of the plant at Kew being white at the time of opening, changing to yellowish-buff as they age. This *Lonicera* coming, as it does, from Upper Burma is of course not hardy, but it is magnificent when grown in a cool house of sufficient size to accommodate it.

The gigantic Birthwort, *Aristolochia gigas*, was exhaling its disgustingly fetid odor in the water-lily house. It possesses larger flowers than any other plant that is amenable to cultivation and is only exceeded by the parasitic *Rafflesia Arnoldii*, which, so far as is known, has never been cultivated. Flowers have been produced on the *Aristolochia* at Kew, 18 inches wide, 22 inches long, with the stringlike appendage 42 inches in length: making the flower 64 inches from top to bottom! The shape of the unopened flower buds inspired the common names "Goose Plant" and "Pelican Flower," while its reputed deadly effect when eaten by swine, was doubtless responsible for the elegant title "Poison Hog-meat."

* * *

Despite unfavorable soil conditions—Kew is founded on barren sand—there are many fine specimen trees, especially in the section occupied by the old Botanic Garden of 1760 which are far too numerous for even a tithe of them to be mentioned. For example there is a tree of our Persimmon, *Diospyros virginiana*, planted in 1762, nearly 70 feet high with a trunk 2 feet in diameter; also a noble specimen of *Sophora japonica*, 70 feet high, one of the original importation of 1753; and many fine examples of the "Ilex," *Quercus Ilex*, an evergreen oak from Southern Europe, one of which is 50 feet in height, with a spread of over 70 feet and a trunk 12 feet in circumference.

Genius gets the world's praise because its work is a tangible product, to be bought, or to be had for nothing. It bribes the common voice to praise it by presents of speeches, poems, statues, pictures, or whatever it can please with. Character evolves its best products for home consumption; but, mind you, it takes a deal more to feed a family for thirty years than to make a holiday feast for our neighbors once or twice.—Holmes.

Sedum—Stone-crop

RICHARD ROTHE

THE number of species of the genus *Sedum*—a member of the order *Crassulaceae*—runs up to about one hundred fifty. A glance over the trade lists from here and abroad shows great divergency in naming and standard works mention synonyms to an extent betraying

Sedum acre

the present chaotic state of the nomenclature of stone-crops. This, in some instances, renders it impossible for growers and the trade in general to absolutely guarantee correctness of name.

Sedums are divided in a dwarfy, low and dense growing evergreen class and a more or less succulent, hardy,

Sedum album

herbaceous class of mostly medium height, species of both classes abounding within the temperate and arctic zones of northern hemisphere. The largest assortment in any of the American catalogs I have seen did not exceed the two dozen figure. By nature they prefer an open sunny rather dry situation, and when well established prove exceptionally resistible to hot weather and prolonged drought as well as to the most severe of even our northern Winters. Many of the low creeping evergreen species have frequently served as a most useful material for covering dry and sandy embankments, where grass growth turns brown every Summer. *Sedum acre*, *dasyphyllum*, *glaucum* and *lydum glaucum*, on account

of their low and dense habit of growth, are the best mediums for filling up crevices of rough slab stone walks and stairwork in formal gardens. *Sedum album*, *Ewersi*, *reflexum*, *spurium* and *stoloniferum* are distinguished by creeping and more spreading growth and, for this reason, best adapted for ground covering on a larger scale.

The best known representative of the herbaceous class is *Sedum spectabile*, the garden form of *Sedum Fabaria*, a lilac-purple flowering native of Central Europe. Of a sturdy erect growth, attaining a height from 15 to 20 inches, the large flowerheads of *Sedum spectabile* in handsome rosy pink or, if we prefer the new variety *spectabile* "Brilliant," in bright amaranth red, are a conspicuous feature in the later Summer and early Fall displays of many of our hardy borders. More recently I have seen this sedum occasionally used for mass effects with surprisingly good results. *Sedum kamtschaticum* and *Sieboldi*, both hailing from the Far East, are special

Sedum spectabile

favorites for dry wall planting, while *Sedum obtusifolium* and the tallest growing of all, *Telephium purpureum*, with their large brown or reddish brown leaves, are very interesting subjects for collectors. All the stone-crops have figured prominently in rockgarden plantings. Being late flowering, their red, pink, white, and yellow blossoms very noticeably brighten color arrays in gardens of our northern states. South of New England vividness of hue diminishes perceptibly. According to my observation the species *album*, *kamtschaticum*, *Sieboldi*, *spectabile* and *spurium*, throughout the Middle Atlantic and Southern States, thrive also in light or partial shade.

Whoever contemplates using stone-crops for ground cover should enrich and prepare the soil to the same depth as required for a first class lawn.

Herbaceous sedums are raised from seed or propagated by cuttings or division. Evergreen species are divided and replanted any time during the growing season.

The nations must be behind the statesmen, and that can only be if the nations are educated to distinguish between right and wrong in international as well as national affairs. Such capacity to distinguish is the ultimate sanction of law.—*Public Opinion*, London, England.

Gardens of Annual Flowers in Shades of One Color

FLORUM AMATOR

THE majority of people, probably, like to have in their gardens flowers of many colors, but a considerable minority prefer to have flowers in shades of one color in their garden, making a more pronounced effect, rather than to have a motley of colors.

The effect of flower gardens in shades of one color is enhanced, however, by edging all of their beds and borders with low-growing plants whose flowers are of a different shade of color bringing out more sharply by contrast the main or body color of the garden. We will mention to illustrate our idea what may enter into the composition of one garden of this kind, for example a garden in yellow, the color of the glorious sun which we all love.

In the northern border of our yellow flower garden in the extreme background we will plant a row of the Chrysanthemum-flowered Sunflowers and in front of these a row each of the *cucumerifolius* varieties of Sunflowers such as "Stella," "Orion," and "Perkeo." The Chrysanthemum-flowered variety, is tall and bears large double, golden yellow flowers with twisted petals; the other three are single varieties with smaller flowers those of "Stella" being golden yellow with a black center, "Orion" yellow with twisted petals like those of a Cactus Dahlia, and "Perkeo," which is a continual bloomer, grows in bush form not more than 12 to 14 inches high and bears miniature yellow flowers. This northern Sunflower border we will give an edging of *Ageratum*, "Swanley Blue," which grows about a foot high, and bears bright flowers.

In another bed we will plant *Hunnemannia fumaricifolia*, sometimes called Giant Tulip Poppy or Bush Eschscholtzia whose Buttercup-yellow, Poppy-like blooms are borne profusely from mid-July till hard frost on bushy plants about two feet high with handsome fern-like foliage. We will edge this bed with *Ageratum*, "Princess Pauline," which grows about nine inches high, and has sky-blue flowers with white centers. We will have one bed of African, and another of French Marigolds, using those varieties only which bear flowers in shades of yellow and we will edge this bed with *Ageratum* "Little Blue Star," which grows about five inches high and bears bright blue flowers.

Surely there must be one bed in our garden of that old time favorite, *Calendula*, "Pot Marigold," or "Shakespeare's Marigold," which during the past few years has become very popular as a florist's cut flower. Of this also we will plant only those varieties which bear yellow flowers and we will plant as an edging for this bed another old time flower, namely, *Myosotis palustris semperflorens*, the true everblooming Forget-me-not, which everybody loves.

In order to have every flower in our garden which bears the common name Marigold we may plant a small bed of *Tagetes signata pumila*, a compact dwarf bushy Marigold with fern-like foliage bearing profusely bright yellow flowers with brown stripes, and since this is a very low-growing plant we will use as an edging the very dwarf *Lobelia compacta*, "Crystal Palace," which has dark blue flowers.

Our bed of *Calliopsis* will embrace only the yellow shades, and that of *Gaillardia* the same shades of color and as these two kinds of flowers resemble each other to a considerable degree, we will use as an edging for

both beds *Browallia nana compacta*, a charming little blue-flowered plant.

The yellow varieties of *Celosia plumosa*, the newer, plumed type of the old time "Cock's Comb," particularly what is known as the *Thompsonii magnifica* strain of the plumed type, will give us a yellow bed of flowers of an entirely different character than the others. This bed we may give an edging of *Browallia speciosa major* whose flowers are a beautiful ultramarine-blue.

Zinnia plants have not a very graceful form but somehow their very primness makes us like them, and a bed of the yellow-flowered varieties with an edging of *Lobelia*, "Emperor William," will add both to the variety and the effectiveness of our yellow garden.

All of our beds so far have been filled with the well known flowers, but we will now fill a bed with a kind of flower not as commonly seen as its merits deserve, namely, with *Bartonia aurea* whose very bright golden flowers appear from June to September. This *Bartonia* grows only about a foot high, and we will edge this bed with *Lobelia pumila splendens* whose flowers are dark blue with a white eye.

Salpiglossis, "Painted Tongue," is becoming popular in our American gardens, and deservedly so, and we will plant a bed of golden yellow *Salpiglossis* of the orchid-flowered strain, and edge our bed of this with another very pretty but in our country too little seen flower, namely, *Viola cornuta* using the dark blue variety, sometimes called *atropurpurea*; if we were planting a blue garden we would have an entire bed of this and of the light blue variety of *Viola*.

One bed in our garden should be planted with low-growing, free-flowering annual, *Eschscholtzia* (California Poppy) preferably with the single variety "Golden West" and the double variety "Crocea" and for an edging to this bed, since *Eschscholtzia* itself is a rather dwarf plant, we should have a very low-grower, and we will again use *Ageratum*, "Little Blue Star."

We now have a garden of yellow-flowered annuals edged with low-growing blue-flowered annuals which will give us a two-fold result, namely, an abundance of flowers in yellow shades for cutting throughout the season, and a splendid display of yellow to greet the eye on every hand as we walk through our garden paths.

One thing is sure, whatever the color of the flowers in our garden may be, we should reserve one bed or border in it in which to grow sweet-scented greens for our bouquets, namely, a half-dozen or more of Rose-Scented and Lemon Scented Geraniums, of *Aloysia citriodora* (Lemon Verbena), a dear old plant the fragrance of whose foliage is fit for angels.

It will be necessary to buy strong plants of the Geraniums and Lemon Verbenas in three- or four-inch pots out of which they can be transplanted into the garden bed. Besides these we should sow a considerable space with Mignonette using the varieties "Allen's Defiance" and "Machet."

It may not be amiss to say in closing that our garden should be dug deeply and the surface soil be made as "fine as silk" and our flower seeds sown in early May rather thickly in very shallow drills and when the plants are still small they should be "thinned out" ruthlessly so that those which are left will stand from three inches to a foot apart according to the kind of plant whether large or small.

Michaelmas Daisies

WILLIAM FOLLETT

WHEN one considers the many good qualities possessed by the perennial asters, commonly known as the Michaelmas Daisies or Starworts, no wonder arises that this flower has been for many years and continues to be very popular in western Europe, and that it is fast coming into its own in its cultivated and improved forms on this side of the Atlantic. It is everybody's flower, being easy to grow; gives quick and good results at a minimum outlay; produces in most cases large, graceful sprays of daisy-like flowers; is unsurpassed for house decoration, and for brightening up the herbaceous borders, shrubberies, and other garden spots.

In the Michaelmas Daisy we have shades of color enough to satisfy all tastes, ranging from the whites and the palest blues through the varied shades of lavender, deep blues and violet to a rich purple; and from delicate pink to crimson, including shades of mauve and lilac so often sought. Two other points in favor of this beautiful flower are its great range of height and the period of its blooming; varying from the Alpine varieties we so often see in rock gardens blooming in May and June and attaining a height of less than a foot, right on to *subcarulea*, the large purple flower with a golden centre, which though borne on its stiff, upright stem in June when there is an abundance of flowers, cannot fail to attract attention. Then with a short break in July, certain varieties bloom on through the Summer and Fall months and often in November. After a frost which has cut down the blaze of colors supplied by dahlias and other more tender perennials and annuals, the Michaelmas Daisy still blooms.

No perennial is more entitled to the prefix of hardy than is the aster, and the fact that the parents of most of our much admired varieties of today are natives of North America should not deter anyone from getting together a splendid collection. The fact of helping Nature to produce better flowers in the locality for which she intends them, should be a sufficient guarantee of satisfaction to the grower.

Although the aster will stand much abuse, neglect in its cultivation is not justified. One can often see a large clump which evidently has not been divided for years, and sometimes the soil itself has passed from the firm stage and become very hard. The Michaelmas Daisy will thrive in almost any soil and situation, but generally does best in a fairly light soil and full sun. The taller varieties benefit by a certain amount of shelter from the wind, but if grown in a wet soil or in too much shade, the flowers are not borne in profusion.

The strong growing sorts are better if divided each year; with the others, every second year will suffice. The best time to divide the clumps is in the Fall as soon as the flowering is over, and when this is done, the beds should receive a good mulching of straw manure and leaves before the severe weather sets in, to prevent the clumps from being loosened and drawn out of the ground by the frost. The litter remaining in the Spring should be removed as soon as the weather opens, the remainder of the mulch being forked into the soil. The clumps can be divided in the Spring, but they would start at a disadvantage to those moved in the Fall, the latter having made nice roots, so that for really fine blooms it is advisable to lift one old shoot of each variety in the Fall and winter it in a cold frame. In early Spring break up the old shoots and sort out the rhizomes, putting three

or four in a four-inch pot and growing along cool. When ready, plant them where they are desired to bloom without breaking the ball of soil. Where mass effect is desired the first year, they should be planted closely; how closely must be governed by the number of spikes to the pot and the habit of the particular variety planted.

When dividing a clump of long standing, retain only the outside portions, the centre of the plant, if not already dead, will only produce spindle-like growth.

When thinking of propagating, it is well to remember that the Michaelmas Daisy can be easily raised from seed. However, as seedlings cannot be relied upon to come true to color, they must be left out of any color scheme. Anyone sowing seed outside, or in a cold frame early in Spring, will undoubtedly derive much pleasure and interest in watching the flowers (often quite distinct from the parent) open in the Autumn, even if he does not secure any decided improvement to add to the already long list of varieties.

Though the plants are sheltered from high winds, it pays to stake the asters. This should be done when the stems are about half their mature height, and if a little care is used in placing the supports, within a week the stakes will cease to be an eyesore. Brushwood such as is used for peas is sometimes employed, but the neatest and most convenient when cutting is to place straight stakes close to the clump and run about a strong, soft string.

Although the Michaelmas Daisy is a native of this country, it was in Great Britain that the work of hybridizing and improving it was first carried on to any great extent. About twelve or fourteen years ago, a number of good varieties were raised, including *acris*, *albus*, *roseus*, *ericoides*, *superbus*, and many more which still remain in spite of new ones each year. Of the newer varieties, one's mind naturally turns to "Beauty of Colwall" which heralded the double form, and with its mass of lavender blue flowers on stems about four feet in height, opening in September, it certainly is a thing of beauty.

For those who prefer pink, there is "St. Egwin" with its lovely shade of pink seldom seen in the asters. It is not quite as tall as the preceding variety but of more bushy habit and is a general favorite. "St. Egwin" is one of the *Novi-Belgii* type as are so many of our best asters. Two other types always popular are the *Novæ-Angliæ* and *Amellus* of which the majority flower during August and September, notable exceptions being the good old stand-by, "Mrs. J. F. Rayner" (crimson), "Baldur," and "King Edward VII" which as a rule open in October. There are so many really excellent varieties it is impossible to name them all, but among the favored are *Novæ-Angliæ* and its varieties *ruber* and *roseus* which often reach six feet high and flower during October and November. In contrast comes "Esme" of the *Novæ-Belgii* class which attains slightly over a foot in height, the compact little plant being covered with large white flowers. *Novi-Belgii*, "Climax," lavender blue, and "Feltham Blue" are deserving of being in every collection, as does also "Mauve Cushion," a dwarf bushy plant which has large mauve and silver flowers in October and November, varying on the same plant from a few inches high on the outside to nearly a foot in the centre of the plant, hence the name.

From Seed to Seedling and Planting

DR. E. BADE

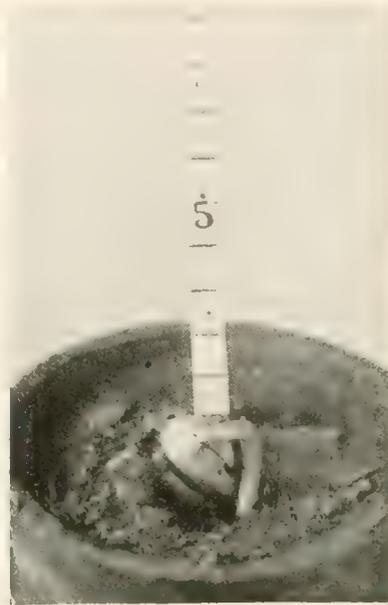

A LONG the old dirt road which winds itself through meadows and fields, a bean has been lustily climbing upon the rough rail fence through the Summer months. How it ever came to this lonely spot, forsaken by all its kind, who knows? At any rate it was still here in the Fall sturdily, twining itself about the woodwork, still flowering indefatigably. It ripened its fruits which were filled with seeds and had no thought for the coming Winter. The first frost of the Fall attacked its vital spark of life, bringing it to its death in one night. The moisture was taken from the leaves by the moody winds. The Autumn sun burned everything brown, even the seed shells and after they were completely dried, they burst. Loosely and white, like shining teeth, the full fruit hung; for their production, the entire life of the plant was devoted. Although the old plant

the seed coat bursts; the tiny root peeks shyly forth, and as they grow larger, they seek for the easiest and quickest way of disappearing into the soil.

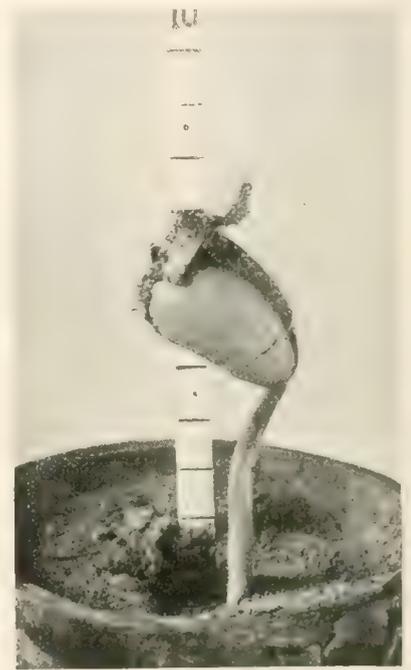

It makes no difference in what position the seed may lie, the root always grows downward. If the seed should lie in such an awkward position that the root must grow upward in order to grow out of the seed, then it grows in a semicircle back to the earth as if it were afraid of the sun. The primary roots have the power of growing downward. This is the result of gravity acting on all parts of the plant organism, and this force requires a growth in the direction of the earth's center, growth in a vertical direction. If under any circumstances the root should be placed in a horizontal position, then the

Germinating bean seed breaking through the soil.

The bean two days later

The germinating seed four days after breaking through the soil.

died in its full development, it had accomplished its purpose in life and the next year will see still more beans twining their green vines about the old fence.

It is a peculiar thing, such a seed. When taken in the hand and examined, it does not show the least trace of life; it seems to be a dead thing, no more alive than the frost killed mother plant. In spite of this the seed is not dead; but only awaiting more favorable conditions under which it can unfold itself. For this dormant life in the seed, the mother plant has fully provided and has worked diligently to give the seed everything that the young seedling may require during the first stages of its life. The embryo is the only thing which is tiny but the food cotyledons between which the seedling is placed, are large and rich. This tiny embryo has its root, stem, and a pair of leaves.

The cold winds of northern storms and the Winter's icy breath pass the seed uninjured. But when the air is balmy and warm, when Spring loosens the moist and frozen soil, then is the period for germination. The seed eagerly absorbs all available moisture; it swells;

force of gravity, acting on the growing cells which lie just back of the root tip, produce a curvature in the root so that it grows downward again.

The root is afraid of, and always turns away from, the light. But that region of the root which perceives the force of gravity is entirely different from that part of the root which resolves the force, or the response of this stimulus into action.

Only the youngest cells of the cylindrical root tip are sensitive to gravity as well as chemical and physical stimuli. This section is only a few millimeters in length, and the response is found at a place about one quarter of an inch above the place of stimulation. Here the root is curved so that it points downward, and this is accomplished by an unequal growth of the upper and lower epidermal root cells. The tip of the root is protected by a root cap which is similar in shape to the thimble of the dressmaker, and it protects the delicate tissues as it penetrates the soil.

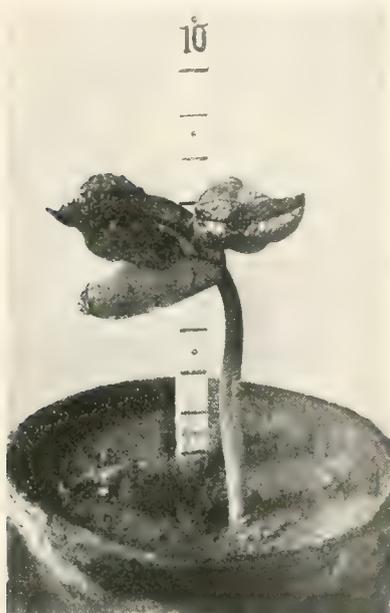

The root fulfills a two-fold duty for the plant: First, it anchors to the soil, and second, it absorbs soil moisture

containing mineral salts in solution necessary for the life of the plant. For the latter purpose the roots have innumerable tiny hairs just behind the growing tip capable of absorbing moisture through their cell walls. The water, containing mineral salts in solution, is transferred from cell to cell until the conducting tissues of the root are reached. From here they are taken to all parts of the plant, especially to the leaves, where, in the presence of chlorophyll, carbon is taken from the air and mixed with the water and salts and thus organic matter is produced in sunlight. Without the chlorophyll found in the leaves, the plant can not utilize the mineral salts in solution of the soil waters.

The young seedling which we have just left through this necessary digression, as it was about to bore its roots into the ground, can not use the salts absorbed with the moisture for the production of food. But growth is not possible without the assimilation of food. Therefore it utilizes the cotyledons and draws its food from them until the first pair of leaves have been fully

finished organic products are led to the various parts of the plant. All surplus water evaporates through the stomata.

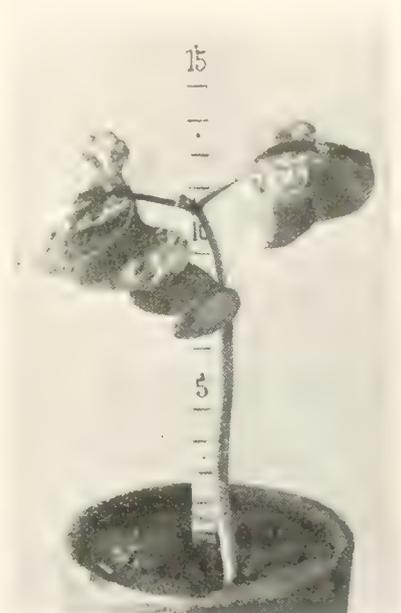

The entire plant consists of a series of carbonaceous products which it has produced but which do not all consist of carbon dioxide and water alone. In the green chlorophyll containing tissues of the leaves, carbon dioxide from the air and water from the soil produce formic acid, an organic substance, and during its manufacture free oxygen is given off as a waste product. Further transformation takes place; the formic acid is changed to formaldehyde and more free oxygen is produced. Finally grape sugar is manufactured. This procedure is dependent upon a sufficient quantity of daylight, and does not take place at night. But the first tangible product produced is starch which is found about the grains of chlorophyll. This starch is the most important product, and from it, the plant does, with the aid of other salts, produce nearly all other plant materials. The most essential are the carbohydrates, sugar and

A day later the first leaves begin to unfold.

The next day the leaves are unfolded.

One day later the new shoot has begun its development.

developed. Now an uninterrupted stream of water passes through the plant from the roots to the leaves, which is then manufactured into food material with the aid of soil salts.

The explanation for the rise of the sap is complicated. It is not dependent upon any one factor but upon many. Some of the more important are the transpiration or evaporation from the leaves which causes the water to rise in the conducting tissues, *i. e.*, it pulls the water upward, the osmotic pressure of the roots which forces the water upward, also the diffusion of liquids and the turgidity of the cell which have their effect. Then there is the imbibing and absorption of liquids through the various membranes of the cell, and the capillary attraction which plays a far greater part than is supposed since the conducting tubes are microscopically thin. There is also the cohesive force of water which, in a very thin tube, as experiments have shown, is excessively large, hundreds of pounds' pull being necessary to force the hairlike column of water apart, etc. The sap, when it arrives in the leaves, is manufactured with the aid of chlorophyll and the carbon dioxide of the air into organic material which is used by the plant for the purpose of reconstructing and building up of new tissues. These

cellulose, then the fats, and finally proteids of which asparagine, especially found in asparagus, is the most important. These three groups are sufficient for the production of all plant organisms.

The wanderings of the products manufactured in the leaves and in other places to those places where they are either stored or used is most complex as the plants do not have an open circulation and transportation system. Transportation must proceed through those closed cells which only too often close the conducting tissues.

The only place where the translocation of substances can be directly observed is in the leaf and the only substance which can be observed is starch. In order that it may be transported from one place to another it must first be prepared for its journey, which is accomplished through enzymes. These are peculiar substances with only partly known chemical composition and having the property of transforming large quantities of material into a soluble form, that can pass through the well wall. This soluble material is changed back again to starch after it has passed through the wall, thus disturbing the equilibrium of the surrounding cells which then pass more sugar into this cell. Therefore the starch is not carried

(Continued on page 17)

Beautifying Home Surroundings

ARTHUR SMITH

IN presenting one or two articles upon the above subject, we propose to deal with it briefly from two main aspects, the underlying principles and the practical carrying out of those principles.

While the whole practice of Horticulture is undoubtedly an Art, that part of it known as Landscape Gardening calls for the fullest appreciation of, and the carrying out of the highest artistic principles. We use the term Landscape Gardening in preference to that of Landscape Architecture, for the simple reason that Architecture, in its proper sense, as being the art or science of building, has in itself no direct connection with gardening. It is fashionable we know in some quarters to use those calling themselves Landscape Architects to plan home grounds, parks, etc., but the term is really a misnomer, as architecture in its true sense deals only with inanimate materials, like wood and stone, and these with other dead things can be combined artistically or the reverse. If one desires a somewhat higher-sounding title than Landscape Gardener there appears to be no objection to that of Landscape Artist, although this may quite as well refer to one capable of arranging colors so as to produce a beautiful picture upon canvass, as to one who can create the same thing upon the surface of the ground by using living plants.

Landscape is eminently a fine art. The enumeration of painting, sculpture and architecture as the only fine arts is seriously deficient, although it has wide currency. A fine art creates organized beauty, unites many dissimilar parts into one harmonic whole. In this respect landscape gardening stands upon a level with other fine arts, and in some respects it even surpasses them. The fact that some who practice landscape art are absolutely wanting in artistic taste does not affect the question, as the same deficiency is to be found among followers of other arts, although unfortunately the landscape gardener or the landscape architect can get away with and get paid for, inartistic work with greater ease than the others.

To some people the art of landscape gardening is only applicable to landed estates and public parks. This, however, is far from being the case, in fact from some points of view, it is more difficult to handle artistically a very small piece of ground than it is an extensive area. The fundamental principles of landscape gardening may be applied to home grounds regardless of their size. No matter how small and modest they may be there are rules to observe if you want your surroundings charming and attractive.

Mrs. Van Rensselaer, in her delightful book, *Art out of Doors*, which deals with the theory but not with the practice of landscape art, wrote: "If now we ask when and where we need this Fine Art, must not the answer be, whenever and wherever we can touch the surface of the ground and the plants it bears with the wish to produce an organized result that shall please the eye. It does not matter whether we have in mind a great park or a small city square, a large estate or a modest doorway, we must go about our work in an artistic spirit if we want a good result. Two trees, six shrubs, a scrap of lawn and a dozen flowering plants may form either a beautiful little picture or a huddled disarray of forms and colors."

A good deal is heard from time to time regarding various "styles" of gardens. Some large places have

their so-called Dutch garden, Italian garden, and so on. To the uninitiated, these names may have a superior sound, but they generally mean nothing, and I have yet to see an Italian garden in this country which has any special or real relation to the typical gardens of Italy. There is of course no particular harm in extensive grounds containing different gardens entirely separate from each other, laid out in different manners and giving them any name one desires, so long as the artistic unity of the whole is not impaired; for after all, "What's in a name?" It does not matter a great deal what kind of designation is given to any particular garden, the main thing to be considered is whether it is artistic and has been laid out with good taste, an harmonious whole, having for its fundamental principle, naturalness; or on the other hand if it contains numerous discords, has stiffness and formality for its basic principles, and is therefore unnatural. Producing a garden of the latter kind is not landscape gardening at all, inasmuch as it has nothing in common with landscape, although such gardens are unfortunately frequently planned by those calling themselves landscape architects. In this connection a definition of real landscape gardening suggests itself namely that it is the art of making a garden which shall be a landscape or picture.

There is no reason why we should not have true art in the garden, and no reason why a garden should be ugly, bare or conventional. The word art as used here is "power to see and give form to beautiful things" and this is based on the study of and love for Nature. The work of the artist is always marked by its fidelity to Nature, and all deviation from the truth of Nature, though it may pass for a time, is, in the end, classed as *debased* art.

There are people who object to the term "natural gardening" as being inexact, inasmuch as no gardening result is absolutely natural, but at the most only naturalistic. While to some extent this may be true, at the same time the word natural is used in contradistinction to that of unnatural, for behind the contents of a natural garden sits primeval Nature, but Nature "to advantage dressed"; Nature stamped with new qualities, led to new conclusions by man's skill in selection, and artistic combination. A natural garden is man's transcript of the woodland world; it is common vegetation ennobled; wild scenery neatly writ in man's small hand, and is Nature's rustic language made fluent and intelligible.

As there is no good picture which does not portray the beauty of natural things, so no garden from a landscape point of view can be good unless it groups living things from a natural way. By this it is not meant that we should reproduce in a garden exact fac-similes of Nature's plantings, but that by adopting the fundamental principles set forth in the wild growth of herbs, shrubs and trees, we shall be able to see and feel everywhere in our gardens the spirit of Nature softened and refined by Art. Whatever the character of a natural landscape, discord is unknown for everything in Nature always harmonizes, and it is in the avoidance of discords that the landscape gardener shows his skill more than in any other way.

In creating a home—by the word home we mean a house and its accessories, with the surrounding grounds—it is obvious that some unnatural features must be introduced,

and naturalness is therefore to a greater or lesser extent lost by the erection of buildings, the making of drives, walks, &c. In the nature of things in the country these features must form part of the home landscape, and it is important that the house, whatever its size, should harmonize with its environment. Too often one sees residences more or less palatial set in the midst of puny, insignificant surroundings, the house being several times too large for the garden, and quite as frequently an artistic landscape is seen to be spoiled by mansions the reverse of artistic and which are merely examples of vulgar ostentatiousness.

A style of architecture suitable for a private house or a public building in a city, or for an institution, where the architectural features of the buildings are the only things to be considered, is quite out of place as part of a landscape. A country house should not only be in harmony with the country, but its size should not be altogether out of proportion to the grounds in which it is set, and it should be as simple and unobtrusive as possible. It is these latter characters which enable such charmingly artistic effects to be obtained when the house is built on the bungalow style, and it is certainly a source of pleasure to all lovers of the beautiful to see that this kind of house is becoming at the present time more popular; apart from artistic considerations, those who have ever lived in a properly designed bungalow prefer that kind of house to any other. The next best style for harmonizing with the country, when a house of more than one story is desired, is that known as the half-timbered. The objection sometimes heard that houses built in this manner are not lasting has no foundation in fact, as we know of many that were built over three hundred years ago which are today perfectly sound.

But after all it is the undue prominence that is given to the house which offends the artistic eye. A country house may be as roomy as the owner considers necessary for his requirements, but large piles of brick and stone several stories tall are out of place in connection with a country home. Many instances have come within the writer's knowledge, where, after erecting a large residence, the owner has expressed himself as being unable to afford to do much in the way of planting the grounds surrounding it; cases of this kind are unfortunate examples of the want of good taste.

In the country the style and size of the house should have some relation to the ground surrounding it, otherwise the creation of an artistic home is impossible. One would not buy a landscape painting in which four-fifths of the canvas was taken up with the portrayal of buildings, although no artist would be at all likely to paint a picture of that kind.

Frequently the landscape possibilities of a home have irreparable harm done to them by the manner in which the house is placed upon the ground, even when such is in itself artistic, and in this connection much good could be done by the designer of the house and the landscape man getting together before anything is done even when the smallness of lot does not leave much room for choice in position.

Then, too, considerable more harm is frequently done to the features of a home as a complete artistic unity by the designer of the house inducing the owner to consent to the erection of more or less numerous *detached*, heavily constructed pergolas about the grounds, a practice which appears at the present time to be unfortunately upon the increase. Among several new homes I have recently come across with this bad feature connected with them, there is one in which the surroundings have been especially spoiled by this means. The area of the place is scarcely more than half an acre in extent and

although the house is really too large for the ground it is an artistic one and constructed in such a manner and of such material as not to present any loud note of discord. But the whole thing has been blemished by four or five pergolas being stuck about. One has been placed in the center of the front lawn and is of heavy timber upon a brick foundation; altogether an element of unnaturalness has been introduced of a grossly pronounced and discordant character. These pergolas or trellises are always irreconcilable with a tastefully laid out garden and are really as bad there as billboards are in connection with natural landscape. When they form part of the house, or are connected with it in creating a covered way over a much frequented walk leading to somewhere they are not so much out of place, especially if so constructed as to be easily and quickly covered with plant growth. While a summer-house is an unnatural feature it may be so placed and camouflaged as to be a pleasant spot in which one may sit and quietly enjoy the beauties of the garden even on a wet day if the roof is rain-proof. On the other hand a summer-house may be, and often is, a very monster of ugliness.

But any of these features, of whatever character or construction, and wherever placed, are always excrescences and points at which naturalness is more or less lost, and which, therefore, require careful treatment and thoughtful good taste to adapt them quite to the best interests of the complete unity of the natural composition.

If landscape gardeners possessing real artistic tastes were more often called in to advise upon the whole scheme of home creation there would be fewer eyesores about the country. More often than not landscape men are handicapped at the onset of their work by what has been done by other people previously to their seeing the place. It is of comparatively little use creating harmonious effects about one part of the home if loud, discordant notes are always in evidence at other parts. The effect of the want of complete harmony thus produced is frequently felt even when the cause is unknown to the individual having this feeling. An estate owner once said to me: "We feel there is something wrong here, but don't know what it is." So long as a feeling of that kind exists it will be impossible for anyone to gain the full benefits from a home in the country that would otherwise be the case as it is scarcely possible for exhausted nerves to gain much vigor when continually surrounded with discords. It is therefore of the first importance to realize that something more than a well laid out and cared for garden is necessary for the creation of a completely harmonious country home.

Desert Vegetation

WILLARD N. CLUTE

If you leave it to the dictionary, a desert is a region almost destitute of moisture and vegetation but this definition does not entirely satisfy the botanist. He knows of various regions on the earth where, notwithstanding an abundance of water, plants are few and far between, and on the other hand, he is familiar with the fact that many other areas, regarded as deserts, may be veritable flower-gardens for part of each year. In the Arctic regions and on mountain tops, for instance, there is plenty of water but in a form which plants cannot use. There are other soils in which a considerable amount of salt prevents the growth of plants, just as we put salt on grass to kill it. Nor are all regions in which there is a heavy rainfall regions of luxuriant vegetation. In many cases the rainfall runs off so rapidly, or sinks so deeply into the soil, or evaporates so quickly that plants can get little of it. In still other regions the moisture may fall during the colder part of the year instead of in the growing season. From these considerations we perceive that a desert is not primarily a region of little water, but a region in which little water is available to plants. There are clearly two kinds of dry soils: the physically dry soil that is actually dry and the physiologically dry soil that may have plenty of water and still be dry to plants. In either case the conditions give rise to desert vegetation.

It is usually the physically dry soil that one thinks of when the desert is mentioned. There are many such in the warmer parts of the earth. They are commonly located behind mountain ranges that cut off the moisture-bearing winds, though sometimes that is due to the fact that the prevailing winds blow from regions where there is little moisture to begin with. The extreme type of such an area in the cactus desert in which only the most resistant plants like the cacti, yuccas, and agaves can exist. The soil here is never covered with vegetation, partly because of the difficulty new plants find in getting started and partly because of the unfavorable conditions for life afterwards. The soil itself is often quite fertile and yields abundant crops when supplied with water as we see in the irrigated regions of our Southwest. Left to itself, however, vegetation assumes very curious and interesting forms. The stems are either condensed as in the various species of cactus, or underground as in the yuccas. Leaves are usually small or absent and the work of food-making is carried on by the stems. When the leaves are present, they are likely to resemble those of the yucca with a hard thick epidermis that effectually retards evaporation. A few species produce thinner leaves during the rainy season and drop them promptly at the first signs of dessication. "Switch-plants" with slender leafless stems naturally abound.

The roots of desert plants spread widely through the soil ready to absorb any moisture that falls and not frequently acting as storage organs for it. In a majority of the plants, however, the storage organs are above ground in stem or leaves which are often greatly thickened for the purpose with special cells for holding the water and a mucilaginous juice to aid in preventing evaporation. Nearly all desert plants have a grayish appearance which may be due to a protecting coating of hairs, scales or waxy matter. The epidermis also may be thickened to form a layer of cuticle and the breathing pores, or stomata, are small and commonly sunk in the tissues of the leaf.

When the desert has a distinct rainy season, large

numbers of short-lived annuals may appear. These spring up, ripen their seeds and complete their life cycle before dryness overtakes them. Such species are usually "rosette-plants" with leaves radiating in all directions from the top of the stem which does not rise above the soil. The dandelion is a good illustration of a rosette-plant in more hospitable regions. Other species with a longer term of life avoid the extreme heat and drouth by casting off their aerial parts during the dry season are retreating under ground, as it were. These are known as "geophilous plants." A few mosses, lichens and fernworts simply dry up until a moist season returns when they resume growth again. Some of these are sold as curios under the name of "resurrection plants."

Extreme dryness, is not the only noticeable characteristic of the desert. Owing to the lack of moisture, clouds are few and the insolation great but the heat is not oppressive because of the general dryness. Because of the absence of moisture, also, the air and soil cool very rapidly after sunset and may become decidedly chilly before morning, even in the height of Summer. The great differences in temperature that thus develop cause high winds which blow the sand into hillocks and dunes leaving large areas absolutely bare of vegetation. Sand-storms, that oblige one to suspend all travel until they pass, frequently occur. The water-courses may be numerous, but they seldom contain water except immediately after a rain. Here and there in the desert, the water comes to the surface in springs or seeps and the adjacent area takes on some of the aspects of more fertile regions. Elsewhere the plants form low grounded clumps and give the whole landscape a tufted appearance.

In desert regions with a distinct rainy period, the cactus desert gives place to very different forms of plants known as *sclerophylls*, with small hard leaves which may be retained throughout the year. The well-known greasewood, rabbit-brush and sage-brush, and various species of *Atriplex*, form the major part of such vegetation forms though there are survivals from the cactus desert such as the prickly pear, numerous yuccas, and the ever-present Mormon-tea or joint-fir. In the direction of heavier rainfall this sort of desert merges into the plains and often contains a number of hardier species of other regions such as the thistle, tumble-weed, evening primrose, milkweed, sunflowers and other composites. The one-seeded juniper and the piñon pine may be found in scattered clumps but everywhere the woody vegetation has a stunted and starved appearance with an abundance of thorns and prickles.

Coming to the deserts of moist regions we find excellent examples in the dunes which the wind often piles up in sandy places. These are deserts due in part to the sterility of the soil and in part to the fact that the rainfall soaks into the soil so quickly. The interior of the dune is often, perhaps always, moist and dune plants have long roots adapted to securing the moisture from an extensive area. A peculiar flora characterizes the dunes. Among typical plants are the sand violet, the hoary pea, the huckleberry, wintergreen, sand cherry, bayberry, sweet fern, bear berry, butterfly-weed, beach grass and such trees as cottonwood, jack pine and black oak. Rosette plants and switch plants are common and mingled with the other vegetation the prickly pear persists.

The cliff is another kind of a desert due to its general

imperviousness to moisture. Though often closely associated, the floras of dune and cliff are usually quite different, though some species may grow in either place. The cliffs support a large number of "crevice plants" which are in reality rosette plants with long slender roots which they send into the crannies in search of moisture. The harebell and various columbines, saxifrages and cresses are typical forms. Here are also found such "cushion plants" as pinks and phloxes in addition to mosses, ferns and lichens. In the cold deserts the mosses and lichens may form the bulk of the vegetation though there are often many cushion plants as well as rosette plants and mat-plants, represented by such forms as the gentians, primroses, phloxes, pinks and the like.

In regions where cold puts an end to plant growth for a part of each year, we find assemblages of plants known

as *tropophytes* or turning plants because for perhaps half of the year they have all the aspects of the plants of perennially moist regions while for the other half they appear like desert plants or xerophytes, dropping their leaves, disappearing underground, existing as annuals and in other ways behaving as desert plants do. Even in warm regions may be found certain kinds of tropophytes that drop their leaves because dryness stops their growth. There is one group of plants that may be represented in both regions. This is the coniferous group represented by the pines and their allies. The slender leaves with thick epidermis are admirably adapted to retard transpiration whether they be exposed to cold or drouth. They are practically desert plants and we may therefore find them on sand dunes, in the cold north, on rocky cliffs or in dry regions near the equator.

Telling Time by Flowers

BERTHA BERBERT-HAMMOND

*In every copse and sheltered dell,
Unveiled to the observant eye,
Are faithful monitors who tell
How pass the hours and seasons by.*

*The green-robed children of the Spring
Will mark the periods as they pass;
Mingle with leaves Time's feather'd wing
And bind with flowers his hour glass.*

(C. Smith).

AS the natural divisions of time are marked by the lunar month and the true solar day and solar year, so the variations in Flora's calendar are recorded by the change of seasons. Note of time is taken by numbers of blooming plants that possess the striking characteristics of opening and closing their blooms at a certain season or definite time of day. The Swedish botanist, Linnæus, observed this peculiarity in over forty varieties of plants, and is said to have utilized this property in forming a unique dial of flowers. Mrs. Hemans comments on the beauty of this idea as follows:

'Twas a lovely thought to mark the hours
As they floated in light away,
By the opening and the folding flowers
That laugh to the Summer's day.

Thus had each moment its own rich hue;
And its graceful cup or bell,
In whose colour'd vase might sleep the dew,
Like a pearl in an ocean shell.

Yet is not life, in its real flight,
Mark'd thus—even thus—on earth,
By the closing of one hope's delight,
And another's gentle birth?

Oh! let us live, so that flower by flower
Shutting in turn, may leave
A lingerer still for the sun-set hour,
A charm for the shaded eye.

Some years ago a gentleman residing in New Orleans who had closely studied this remarkable property of plants, constructed in his garden, which contained interesting plants from nearly every clime, a large floral clock in which are massed and carefully arranged in a circular bed twenty-four kinds of plants, each variety being planted

opposite to the hour at or near which its flowers would open. In this dial, the *Portulaca* which was chosen to represent twelve o'clock is said to have never varied more than ten minutes of the noon hour in the opening of its flowers. The old-fashioned Four o'Clock, dependable to represent the hour indicated by its common name, was planted in the proper position and the *Nyctago* was planted at five. The Evening Primrose appeared at seven and the evening hours were assigned to night bloomers, the midnight hour being graced by the *Cactus* known as the Night Blooming Cereus. Though not a part of the time-telling scheme, a large pair of vine-covered, wooden clock hands were added to give a more realistic touch to the design.

In more recent days, a French botanist is said to have carried out the bright idea of a floral timepiece by laying out a circular flower bed of twelve sections, intended to mark only the twelve daylight hours, beginning with the opening, at about seven in the morning, of the water lily and ending with the opening of the Evening Primrose.

If desired the idea could be worked out to a greater extent by noting also the span of life enjoyed by the various flowers utilized. By careful observation of the opening and the closing habits of plants, it is thus quite possible to construct a floral dial that will prove a fairly accurate time keeper.

FROM SEED TO SEEDLING AND PLANTING

(Continued from page 13)

in an unbroken stream of sugar but it is deposited and redissolved as it passes from cell to cell. In this way the starch is finally brought either to a place of storage, or to where it is to be used. It is probable that the proteids behave similarly, but they can not be observed.

The organic materials necessary for plant nourishment are not used without a change taking place; through chemical work they are turned into new and manifold products, a few of them being now made synthetically in the laboratory. The plant can not turn starch or sugar directly into proteids with nitrates or sulphates. Without a doubt many intermediate steps are necessary before the final product is reached. But the "how" and the "what" are still problems for the future.

Bonsai: Culture of Dwarfed Trees in Japan

KIYOSH SAKAMOTO

THE Japanese people love to rear flowers and herbs in a porcelain or earthen pot. Such a culture is distinguished by the name of "Bonsai" (literally, pot-cultivation). This domestic horticulture is a favorite hobby both for high and low throughout the length and breadth of the Empire. As for the size of the pots, used in this special art, these range from large ones to be carried about by several strong hands to small ones that will roll off at a slight push with a single finger. A pot portable with two hands is the most general size, as is easily inferred from the nature of the art.

The secret of the delight of "bonsai" lies in the reproduction of a piece of natural scenery in a tiny spot. Seen in such a light, mere rearing will not serve the purpose. A plant must be made to appear in a pot as if it were standing on a hillside.

"Bonsai" embraces many methods with special names respectively, according to kinds of plants and their different ways of rearing. For example:

(A) Solitary style: a single tree set up straight and towering in a pot.

(B) Twin style: a tree parting at or just above the root into two great trunks and looking like the letter "U" or "V" at a little distance.

(C) Bristling style: many branches coming up from the same trunk, with the appearance of a brush laid in a pot.

(D) Promiscuous style: several trees or plants of the same kind or of different kinds mixed so that a little piece of ground in a pot may appear like a plain or a hill.

(E) "Neagari" style: a fork-like root peeping high about the ground.

(F) Cliff style: the trunk and branches bent downward as will be seen on the surface of a hillside or a cliff.

(G) Half-cliff style: this is a mixture of a combination of the solitary style and the cliff style.

(H) Embracing style: a tree planted on a piece of rock and the foliage embracing the rock.

Pots to be used in "bonsai" should be carefully selected, and the choice depends upon contours and colors of plants. The pot and the plant must harmonize with each other. If you fail in this first step, the finest plant and the costliest pot will avail nothing.

Pots are as a rule of porcelain, or earthen. Their shapes are circular, square, oblong, oval, etc. Unfigured pots are in great favor. Dark-brown color is most desired. These dark-brown pots originated in China, but recently many imitations have been produced in Japan.

(a) The plant which harmonizes with an oval or circular pot must have a round profile, no ins and outs being seen along the lines from the top to the lowest branches.

(b) The square-shaped pot wants the plant to be long-branched in its lower part and remarkably short-branched in its upper part.

(c) The deep-bottomed pot is used to fit in well with the "cliff" style plant.

(d) *Rodea japonica* and the orchid are proverbially planted in the pots of genuine Chinese make.

(e) Water-plants and sea-weeds are placed in water basins.

Judging from the aforesaid statement one might imagine that "bonsai" costs pretty dear, quite beyond the reach of those of moderate means. Far from it. A pine-tree which you get for a few cents, if planted properly in a pot, will prove a feast to your eyes. The essence of the art lies in cultivation and method of protection. You will become a skilled "bonsai artist" only after many years of close study and experience.

The plants to be used in "pot horticulture" had best be reared from young sprouts. By this means you can control them in any way or form you like. Young

sprouts can be had on occasion of your rambling in the fields or mountains. If you tend them with care for three years, you will be blessed with a little luxury for your eyes. Two years more, and your favorite plants will be the center of admiration from your friends and neighbors.

The sprout must have a shapely contour and fantastical branches. Its lower branches and the root are expected to be specially strong. The trunk should be as straight as straight can be. According to such a standard selection must be made.

The young plant is to be placed first in a rough-baked earthen pot. Such a pot makes irrigation easy and seldom spoils the root by the stagnation of water or fertilizer in the soil. Yet in Summer watering is indispensable at least twice a day.

The sprout, fresh from plain or hillside, usually has a straight root. When you transplant this into a pot, you must not forget, first of all, to cut to a proper length and then put the plant into a deep pot after the remaining root is coiled. The soil in the pot should be a compound of 60 per cent of ordinary soil and 40 per cent of decayed leaves; if the plant is taken from a deep valley among large mountains. If the plant happens to hail from a hillside near a village, 80 per cent of ordinary soil and 20 per cent of horse manure will afford a suitable culture medium. After all, the soil should be kept as near as possible to the natural soil native to the plant. A sprout that is one or two years old requires more fertilizer than its older brothers. If the sprout grows old enough to be provided with "chief" branches, "small" branches and "bag" branches (these three kinds of branches are indispensable elements in forming a piece of "bonsai" art), the next step to be taken is to transplant the plant into a larger pot. If you leave your plant in the pot too long, it will have its upper boughs strong and its lower boughs weak. On the other hand, to transplant it when too young is out of the question.

In the process of final transplantation special attention must be paid to the position of the plant. If you fail in this part of the procedure, you will do gross injustice to your pot, however much of a rarity it may be. If the top of the plant tends to the left, you should set it a little to the left side of the pot, and *vice versa*. To place your plant just in the middle of the pot is the last step you should think of taking.

To plant one tree in a pot is an easy thing, but to place two trees requires much skill and fact. In such a case you should select a tall tree and a little shorter tree. These two are to be planted, one a little nearer to represent a forest in miniature in this small world of a pot. The maximum to be used in a pot is ten plants of one genus.

The soil in the pot should be so heaped that the part where the plant peeps above the surface is the top of a small mound. The root of the plant appears a little above the top. The foot of the mound is a little lower than the brim of the pot.

To cover the surface of the soil with deep green moss largely contributes to the elegance of the potted tree. There are mosses and mosses: for example, the mildew-looking moss which grows on a forest tree among mountains, the beard-like silvery moss which is found on the shady side of a trunk, and what not. Whatever kind of moss you may select, the first thing you should keep in mind is to reproduce Nature in the pot.

If you find a group of moss suited to your purpose, shake off the clinging earth and dry it in the sun. The next thing to do is to tease apart the gathered moss easily and scatter it on the surface of the soil and give it a little watering. A good rain or two will deck the pot with a piece of verdure. It takes not a small quantity of time and labor to improve the appearance of a plant.

In Spring when the sprout begins to branch, you must take away all leaves except the upper two. In about a month new sprigs will come out, but these again must be got rid of. The remaining twigs will develop enough to bear some minor twigs.

The infancy of a plant is the best time to correct or straighten the ill-shaped branches. If you happen to find a sprig growing just where you wish it to come out, see that the sprig be tended with more than usual care, cutting off all other unwished-for twigs and thus making it easier for the pet twig to become large.

Spring is the season when the circulation of the plant-juice is most active; and so this is the best time for transplanting. Every "bonsai-ed" tree, whether it is growing on natural soil or in a pot, requires transplanting at least once a year. The following is one way of transplanting:

First of all, wash the roots clean. If you find any decayed matter among entangled threads on the roots, take that away, together with mould, which you will surely come across when unearthing a plant. The washing done, dry the roots and then set the plant in a pot. Take the pot out of doors in the day and indoors at night.

In Summer the scorching sun dries the soil rapidly and frequent watering is necessary. But beware of giving too much water at long intervals. Whenever you see the soil dry, don't neglect watering your pet plant. To tell you the truth, water somewhat prevents the plant from wearing "antiquated" color, but insufficient water soon kills the plant.

Transplanting can be done about the time of the autumnal equinox without impairing the beauty of your tree. But the sprouts coming out at this time ought to be nipped or they will mar the graceful appearance of the tree in Winter.

Watering should be avoided in Autumn lest it should rot the roots.

Those trees which turn red, such as maple trees and wax trees, are specially lovely in Autumn with their crimson leaves. If you want to retain the gorgeous color on the leaves, take care not to expose the tree to rain or dew after it begins to be tinted. When the dwarfed tree undergoes "hibernation," so to speak, the only care you should take of your pet plant is to keep the soil in the pot from freezing. For this purpose place the pot in the sun on fine days with a little watering before or after the noon.

The most effective way of fertilizing is first to make a slight hollow circle, two or three inches in diameter, around the root, and then pour fertilizer into this hollow on fine days. Just before the sprouting period and the period of propagation is the time when fertilization is more necessary than at other periods. When giving fertilizer to your tree, do not apply too much at a time, but give the plant its nourishment little by little. Old plants require more fertilizer than young plants.

For watering purposes, rain is most suitable; next comes the water drawn from the river. Water fresh from the well is not so welcome to the plant. The older the water, the more nourishing it is.

Trees adapted to this special kind of culture can be grouped into three main classes. If we add some shrubs that can be cultivated as pieces of "bonsai" art, we have

four kinds in all, namely, "leaf-cultured trees," "flower-cultured trees," "dwarfed trees" and "herbs." Space does not permit the giving of detailed description of the different methods of culture, according to each of these classes. Therefore I will here epitomize some of the most popular ways resorted to on this side of the Pacific.

In "bonsai" art red pines are in high favor, as they can be very tastefully cultured. They like to be planted on the red soil. The shelf on which they are placed should be set up in a well ventilated part of the garden. Beware of exposing them to rain. The soil should be kept as dry as possible and fertilized with powdered oil-cake.

Maple trees must be placed in a shallow pot. The soil to be used for them is red soil or mountain soil. They want much water. Therefore frequent watering is necessary. Fertilizer should be as thin as possible. If you leave the trees in the scorching sun in Summer, you will get the tips of their leaves brown. After their leaves have all fallen, their bare branches present a most graceful aspect.

The cedar tree has so many small branches that it is an easy matter to train it as you choose. The use of fertilizer is not necessary, but watering must not be neglected, as the tree likes wet soil. When you plant a cedar tree in a thin pot you have a deep valley in miniature before you.

The elm tree also branches profusely. Look at the tree after all its leaves have fallen. Even then you will find the thick branches interrupt the view beyond. In course of cultivation the root will become, in too many cases, thicker than the trunk. Then cut away the root, leaving about three inches from the top of the root, and transplant it in another place. Such a process will have the result of more small trunks coming up from the root, which is exactly what the "bonsai" artist wants the tree to do.—*The Canadian Horticulturist*.

"Truth," said Corot, "is the first thing in art, and the second and the third." But the whole truth cannot be told at once. A selection from the mass of Nature's truths is what the artist shows—a few things at a time, and with sufficient emphasis to make them clearly felt. You cannot paint Summer and Winter on a single canvas. No two successive hours of a Summer day are just alike, and you cannot paint them both. Nor, as certainly, can you paint everything you see at the chosen moment. Croud in too much and you spoil the picture, weaken the impression, conceal your meaning, falsify everything in the attempt to be too true. Corot managed to paint to interpret life, mood and meaning of what he saw.—*Mrs. Schuyler Van Rensselaer*.

A PRAYER

Nettie Orcena Wolfley

Dear Father, tend the garden of my thoughts,
 Thy dearest care,
 And uproot every weed and flower Thou hast
 Not planted there.
 Give me, to keep my paths and borders straight,
 Thy Golden Rule,
 To fashion them like his who left for men
 No sharper tool.
 Teach me to know at sight, in any guise,
 One noxious weed,
 The "root of bitterness" which, spring up,
 Bears evil seed.
 Warm with the sunshine of Thy love the soil
 Around each tree
 That, looking from the earth up toward Thy light,
 Bears fruit to Thee.

Chloe S.

Leaf Falls Without Frost Bite

AFTER a night's sharp frost in Autumn we are not surprised when we take our walk to see the ground littered with fallen leaves from every shade of yellow to hues of the deepest red or brown. In fact, we look expectantly for this sudden spreading of a leafy carpet as a natural sequence to the change of temperature, and quite as a matter of course we attribute it to the work of the nipping frost.

Before we take things so absolutely for granted let us take a little closer look into the matter and see what really takes place; for, after all, in their own good time surely the leaves would have fallen, even though the frost had never been.

Again, in tropical countries where rain does not occur for several months at a time plants act in an exactly opposite manner to those in our temperate regions, for their leaves fall before the hot, dry season, while in climates where no lengthy and alternating periods of hot and cold occur the "fall of the leaf" is a very inconspicuous event, as new leaves form and develop at the same time that the older ones are falling away, so that the trees appear, more or less, to be always in full leaf. Evergreens, in our own climate, present a somewhat similar case, but even these have to shed their leaves sooner or later, although in some cases they may last for several years.

It would, therefore, appear that some other potent factor or factors besides cold and frost must be at work at the time of leaf fall. Before we can make any progress toward this end, however, we must assimilate one important fact, namely, that the great engine which provides the motive power of all life, both plant and animal, is sunlight.

Now the leaves of plants are organs especially constructed to intercept rays of sunlight; every leaf of every plant is adapted, so far as circumstances and environment have permitted, to present to the sunlight as much surface as possible, hence we get endless forms of leaves on different species of plants, those forms fittest for the environment naturally surviving.

DIE BEFORE TROPIC DRY SEASON

Leaves are continually transpiring watery vapor from the stomata, or openings on their under side; this transpiration is, of course, kept more or less active according to the dryness of the surrounding atmosphere. In very hot weather it is apparent that transpiration would be most active, and this at a time when most inconvenient to the best interests of the plant, for then the soil would be so dry that it could not supply the increased demand made upon it. Hence it obviously follows that if a plant growing in a hot climate could dispose of its leafy raiment before the dry season, and so largely shut in the store of moisture that it then possessed, it would be adopting a most protective measure. Such is the way, then, by which, when the water supply begins to fail, such plants prepare to meet the situation, and, in due course, when the dry season arrives their leaves fall and the so-called "Summer sleep" commences.

Later in the season, when moisture again impregnates the soil and the water supply within the plant is naturally very low, the mineral salts in the plant tissues greedily absorb any moisture that comes their way, and so the young roots are incited to seek for greater supplies.

If the "fall of the leaf" before hot, dry periods can be so explained, what of our climate, where the exact opposite, a long, cold and damp period, occurs. We know

that the leaves fall before the Winter sets in, but that their fall cannot be associated with a lack of moisture is obvious. What, then, is the influence at work in this case?

Let us suppose that we have a delicate, sensitive plant growing as a pot plant and that we water the soil in which it grows for a few times with very cold water. Although the surrounding atmosphere may be most favorable to its development and the temperature of the soil well above zero, yet we find that the leaves of our plant begin to flag and soon the whole plant looks as if it had been nipped by the frost. What has happened? The very cold water has lowered the temperature of the soil so much that the activity of the roots has been interfered with, and as a natural consequence their absorbing powers have decreased. But the leaves in the warmer atmosphere above have gone on transpiring aqueous vapor as usual; thence the tissues have lost their water and it has not been replaced. So the plant shrivels up and dies.

At the same time also by disposing of their leaves trees avoid other serious dangers. Water in the tender tissues of the leaves during the times of frost would be most dangerous to the plant structure, for then it would become ice and with the expansion that takes place when water freezes the tissues would be ruptured. How dangerous such an enemy would be to the delicate vegetable cells can be readily demonstrated by the bursting of a water pipe when the water contained in it expands in the process of freezing. Another danger, overcome by the absence of leaves, is that of heavy falls of snow. Trees covered with foliage during heavy snowstorms get their branches sadly broken by the weight and the pressure of the wind.

It should be observed too, that trees in the lowlands retain their leaves several weeks longer than those of elevated mountain regions, even when of the same species. In the latter situations snow and frost often occur in the Autumn months, and consequently the soil is cooled sooner than that of the lowlands. From this we might suppose that these mountain plants would have to put forth their leaves several weeks earlier in the year than their lowland relatives. As a matter of fact, the exact opposite is the case, for the mild temperature of Spring is later in reaching these elevated regions; hence it comes about that in these colder regions those trees survive best which have adapted their season's work to commence a few weeks later and finish a few weeks earlier than the normal period.

PURELY PROTECTIVE MEASURE

We may reasonably assume that the "fall of leaf" is chiefly a protective measure adopted by the plant against transpiration at times when it would be injurious to its economy and that it is brought about by either heat or cold. At the first indication in late Summer of a lowering temperature some peculiar layers of cells begin to form at the base of the leaf stalks and quickly extend across the tissues, disconnecting them. — *New York Sun*

Flowers have an expression of countenance as much as men or animals. Some seem to smile; some have a sad expression; some are pensive and diffident; others again are plain, honest, upright, like the broad-faced sunflower, and the hollyhock. — *Henry Ward Beecher*

Work for the Month in the Garden

SAMUEL GOLDING

WE have now crossed the threshold of a new year, and the thoughts of garden lovers go forward in anticipation to the joys and pleasures of achievement during the coming season. The history of horticulture during recent years has been remarkable for the improvements made in many types of flowers and vegetables, and the ever increasing interest displayed by the general public towards home gardening, to which fact the various societies and garden clubs that are being formed throughout the country, bear eloquent testimony. They are conducive to that which is good in the advancement of horticulture; their exhibitions not only promote a wider knowledge of flowers and plants, but are also the "happy hunting ground" for the amateur and professional who is ever seeking for that which marks an improvement.

The pleasures of gardening are not confined to a fleeting month or two but extend throughout the year, even when our gardens are wrapped in sleep. A retrospective view of the year's efforts and an examination of notes taken at the various shows will now be in order. At this time the really successful grower will be forming plans for the coming season's campaign. Notes written last year for future reference will be of the utmost importance and will remind us forcibly of any failures of crops, or of any particular vegetables which proved their worth; of varieties of flowers whose colors may not have been of the desired shades, or of others that deserve to be grown increasingly; of other out-standing features noted so as to gain advantage of past experience and apply it during the following season.

The note book does so much also to simplify the work on the seed order which must now be attended to. Some varieties of vegetables previously grown may not have found favor with the person in charge of the culinary department. Take for instance, the case of a grower sowing seeds of red, yellow, and white onions, when White Globe alone are appreciated. This is a common occurrence, and if a record is kept, it can sometimes be eliminated and the value of the crops increased.

It is an excellent plan to make out a complete list of seeds, plants, fertilizers, tools, spraying materials, and any other supplies which may be needed, and to order them early so that they will be on hand when actually required. Delays often cause disappointments, especially so if the stock of some particular variety we have decided upon, is short and quickly sold out.

The beginner will be well advised to commence with those varieties which are known to thrive in his locality. As for novelties, it is right to try them, but not to bank on them. Older and well tried standard varieties can generally be relied upon. Procure your seed from a reputable seedsman; the initial out-lay may be a trifle more but the high germinating quality more than compensates, for they can be sown sparingly with greater confidence as to the final results.

The stock of vegetables and fruit will need attention, and all specimens showing signs of decay should be removed. Many have to store their crops in cellars where there is the heat of a furnace to contend with, if the space is limited. This causes a too dry atmosphere, which should be avoided. Care in such cases should

be exercised and stocks of dahlias and other bulbs should have frequent inspections to prevent shrivelling and consequent loss of vitality.

Should we have a spell of mild weather, it would make it possible to remove the covering and expose the tops of celery, which is wintering outside. This will allow the moisture to evaporate, but celery must be protected at night in case of a sudden fall of temperature.

Continue to bring in a succession of rhubarb, seakale, chicory, and asparagus for forcing. They should be kept in a cool place, and will then respond quickly when brought into heat. Seakale and chicory must be grown where the light is excluded to be blanched perfectly. Care and attention will be needed regarding the watering that a moist, growing atmosphere may be maintained.

Mushroom beds that show that their vitality is becoming impaired, may be watered with tepid water in which a handful of common salt has been dissolved. This often has an invigorating effect upon the beds. Use a fine rose can when watering the beds. We can now continue to gather material for new beds, which is an easy matter when there is an abundance of horse-droppings. Collect enough at one time to make beds of the desired dimensions, which should be turned over daily to sweeten the mass thoroughly. This can only be accomplished when the violent heat has subsided and the strong traces of ammonia have disappeared. Take care to beat the beds down firmly, and after a few days, they will be ready for spawning. The next step is to cover the beds with some good loam, pressing it down with the back of a spade. Mushrooms can be looked for about six weeks later.

Apply winter spray to fruit trees as advised in last month's calendar, and push on with the pruning of the orchard when the weather permits. Evergreens and the flowering shrubs suffer from the ravages of scale and other pests, if they are not carefully examined and sprayed. Be careful to shake snow from over-weighted conifers and evergreens during heavy falls.

FEBRUARY.

The growing of early vegetables under glass demands attention although the early days of February may be regarded as almost too soon for the person who has not the facility that the greenhouse affords. But the lengthening days with increasing sunshine serve to remind us that the growing season is once more rapidly approaching. Therefore we should make all preparations to meet the near demands. Where only pits and frames are available for early work, the preparation of materials for hot beds is the first to occupy our time. This can be done as soon as possible. Collect plenty of fresh, strawy, stable manure and mix it with the same proportion of forest leaves, oak or beech leaves preferred, owing to their lasting qualities. This mixture should be turned over thoroughly to ensure a steady heat. It is, of course, important that the material be in proper condition when used, which can be determined during the time of turning or mixing. If the manure has been allowed to ferment violently before being used for the hot-bed, it is not as good as if it were fresh from the stable. Apply water

(Continued on page 23)

The Greenhouse, Month to Month

W. R. FOWKES

JANUARY and early February is a very interesting period in greenhouse work. Winter's chilly hand has seized all outdoor subjects, but the colors of the indoor blooms are intensified. Hard firing is in progress, bringing in its wake red spider. We must combat this pest, and not allow too arid an atmosphere in any part.

The rose house should be dampened down if the floors are of cement. Take care that water permeates the entire bench of roots where the heating pipes are under the benches, or the plants will suffer severely. Try and keep the rose house at an even temperature of 60 degrees at night, or a lot of foliage will be lost. Day temperature can be regulated more than the night, and the sun's rays will be more frequent and powerful now than in the last eight weeks. If kept too cool now, your crops will be short, for the wood will harden and go to sleep. Do not topdress, but give a fair sprinkling of bone meal now. It will carry the plants along their Winter's journey without anything else.

Carnation cuttings should be inserted in the sand and will strike now far better than two months later. Remember the kind of cuttings to make. The nearer the flower you take them from, the more prolific crop of flowers you will cut next Winter. It is likewise important to avoid the usual method of trimming tops of the cuttings. Many cases of stem rot have their beginning through the bruising which is caused by this method. Every one should grow the dark pink carnation, Hope Henshaw. It is the most prolific bloomer I have ever grown. The stem and blooms are of wonderful size, and the blooms are never off color.

The early peaches in pots should be brought into a cool house. Spray well to counteract scale. Keep the temperature for the first week as near 38 degrees as possible, and as the buds swell, increase, but never allow higher than 48 degrees until the fruiting period is at hand.

Lilacs for Easter should be started. See that scale is not introduced by bringing these plants indoors. Scaline is the best eradicator of this pest.

Among our friends the orchids, *Cattleya Percivaliana* and *Trianae* are the first to herald in the New Year. They come at the period when orchid blooms demand the highest price. The late Fall weather with its unusual warmth and sunlight has benefitted these plants, and where the shading was taken off carefully from time to time, we find the result in most plants is that they are sending forth a good supply of fine blooms. *Cattleya Mendelii* which blossomed in May, made quick and successful growth, and with us is giving its second crop of blooms. If any of these plants need repotting, they should be attended to now. Clean pots and make a compost of osmunda fibre 3 parts, 1 part sphagnum moss and plenty of crocks for drainage.

If your orchid house is low, you will need a little shade on the sunny side, or your new growths will be ruined. There are a lot of orchids in bloom and at various stages of growth at this time, and it is not unusual in the United States to cut two crops of blooms per annum. Unlike European culture, with restricted sunlight, orchids here, excepting deciduous calanthes and dendrobiums, are practically never at rest. Rest here in this sunny climate is rare and the person who denies against certain

methods and wants special houses in which to grow orchids is not in sympathy with their natural desires. The skill of the cultivator has more to do with successful culture of orchids than any kind of greenhouse erected.

Ferns should be divided in early February. They then have their period of new growth and can be divided into as many sizes as one requires. Compost is not very important, but drainage is most important. The *Farleyense* tribe favor heavy rose soil and red sandstone incorporated. The usual *Nephrolepis* and *Adiantum* will grow taller if desired, in light soil containing leaf mold.

Repot *Schizanthus* when necessary and sow a little now of Badger's hybrids. When in the flowering size, five or six inches, be careful not to over water.

Bring *Spiraea* along gently on a light bench in a cool greenhouse. See that your gardenias are free from mealy bug; also that they have free drainage or the result will be sickly foliage which some people wrongly believe is due to their being grown inland, claiming that this class of plants only thrives on the sea coast.

Crotons should be tongued. Take any bushy plant and cut off the lower leaves on a healthy shoot; make an upper slanting cut and half way through put a tooth pick or smaller piece of wood to keep incision open, and insert a little moss and sand previously chopped up fine and moistened, and secure with raffia. Keep in a warm corner gently sprayed away from draughts, and in six weeks you will have a nice lot of young plants for 2-inch pots. Successful croton culture consists of slight shifts. Never give more than a half inch shift in repotting and this should be done very firmly. You can build up plants fully six feet in one year from early struck plants.

Chrysanthemums of the large type should be put in the sand in February. The pompoms and others will be early enough for pot use if struck the end of March. The propagation is simple. They will strike readily in twenty days time if the sand is 60 degrees and the house between 50 and 60 degrees.

Pinch back any poinsettias left from Christmas time and you will develop a nice growth that will bloom well at Easter.

Sprinkle a little tobacco dust around the roots of cauliflower plants to kill the maggots that infest these occasionally.

Do not waste valuable space in your houses propagating roses from cuttings. Order grafted stock from the special rose men who advertise in the GARDENERS' CHRONICLE, and who will deliver them when they are desired next Summer. The coddling which one's own rose roots demands; the wearisome waiting for a crop of blooms; the continual dropping of yellow leaves if your atmosphere and soil, etc. is not just so, combined with poor substance of petal, just takes the joy out of indoor rose growing. The grafted plants have a vigorous start which they maintain, and you can commence to cut very nice blooms eight weeks after planting. They will continue doing so with a little manipulating of the buds. On your present crop take away two buds off every plant each week, buds just showing color, and you will never be without roses, but be sure to secure grafted plants next year.

Cuttings of lantanas and Bouvardias should be inserted, but use very slender growths and be careful to keep shaded from sunlight.

Cut all flowers rather earlier in the day than you did a few weeks ago. There is plenty of ice to be had now for the ice box and if you have a cool cellar you will not require ice. But avoid gas from the furnace. A too frequent cause of carnations going to sleep after being cut is from coal gas. Orchids are very easily injured by it also.

Do not be in too great a hurry to force tulips. They detest heat, and the antirrhinums you grow with their long stems are more suitable than stunted tulips. They will come along all right later.

Give the freesias a little Clay's fertilizer. Cinerarias and cyclamen will appreciate a little also now that the soil is getting exhausted. It is not how much feeding plants will stand as amateurs frequently ask, but when the plant requires it, that helps in successful culture. There is not a plant grown that will not benefit by judicious feeding.

Soot water once a week for the palms is now appreciated. The palms that were not repotted will develop fine foliage if given a dose of Dried Blood, a tablespoonful to a 10-inch pot. Be careful when watering not to wash it away carelessly. Between several batches of palms repotted a year ago and a batch fed in the manner described, I can see no difference, and time and labor is saved in not repotting.

Keep all foliage plants in as small pots as possible. They will take more water and fertilizer and be more convenient to handle.

WORK FOR THE MONTH IN THE GARDEN

(Continued from page 21)

from the hose if it appears too dry, and moisten it throughout. When it is fermenting evenly, make the bed, the depths of which must be determined by the conditions under which the particular crops must be grown. It can usually be regarded as false economy to adopt a sparing policy with the hot-bed. When filling the frame, bring it up as near the glass as possible and tread firmly, so that when it has sunk to the full extent the plants or seedlings will be located where they can enjoy to the fullest extent the sunshine and air, which they require for perfect health. If it is intended to grow only seedlings in the hot-bed, use a much smaller percentage of leaves; the heat is stronger. Cover with a good compost to a depth of four to six inches, according to the plants raised. When the heat has subsided to a uniform steadiness, sow such crops as early carrots, beets, radishes, and lettuce.

Give air whenever possible to plants wintering in cold frames, or they may, during mild spells, start into premature growth. Keep the plants free from decayed foliage and water very carefully.

MICHAELMAS DAISIES

(Continued from page 11)

The *cordifolius* type is worth growing, if only for cutting. Its small flowers on long, graceful sprays are adapted for vase work. "Sweetheart" is recognized as being one of the best.

The Michaelmas Daisy because of its varied height and color can be planted to advantage in many ways. It is ideal for growing between Spring flowering shrubs for it soon fills up any gap caused by pruning the latter and

with Summer and Autumn flowering shrubs, keeps that part of the garden bright until frost comes. Planted in large beds with *helianthus* "Miss Mellish" or *Tomentosus*, present a very good effect. Another effective combination is obtained by planting Michaelmas Daisies with the *Boltonia*, mixing the pink and blue shades with *B. asteroides*, and white flowering varieties with *B. lat-isqueama*. (*Boltonia* vary in height from nearly four to seven feet.)

This flower also shows up to advantage in front of a wall or trellis covered with English Ivy, Honeysuckle *Halliana*, or *Pyracantha Lelandi*. Planted in a wide border with a tall hedge of Holly or Yew at the back, as is so often done in England, the Michaelmas Daisy seldom fails to produce a most striking and artistic effect.

In nearly every cottage garden in England, can be seen the Michaelmas Daisy—hardy aster—and at the Autumn shows special classes both for the amateur and professional are arranged for this flower. Each year new and improved varieties are eagerly sought for and as long as that progressive spirit is retained in horticulture, there will always be flowers worth while and amongst them, the Michaelmas Daisy.

GARDEN PESTS AND REMEDIES

WEEDS decrease our crop yields to such an enormous extent, they interfere so seriously with our farming operations, and they cause such tremendous losses in dollars, that concerted effort should be directed to their reduction and eradication. Any community, large or small, that sets itself the task of practically eliminating its weeds and adopts and sticks to a program of action, can work wonders. It is quite certain that everyone knows what a "weed" is. Probably no one of us has had the term defined but our conception of its meaning is very clear. It may be that at one time in our early days we were told to pull the weeds in the corn field or garden; to mow the weeds along the fence; and at such a time it is certain that no words of explanation were needed to indicate which the weeds were. We have come to consider as "weeds" those plants which tend to grow where they are not desired; plants which tend to resist man's efforts to subdue them; plants which resist frost, heat, dryness; which will grow in almost any kind of soil and under all conditions; plants which produce seeds in enormous numbers and have other rapid methods of propagation; plants in themselves sometimes truly beautiful, but that have for us lost their charm; plants useless and troublesome. Emerson said of a weed: "A plant whose virtues have not yet been discovered."

A large Purslane plant will produce 1,250,000 seeds; a single Russian Thistle plant will ripen 100,000 to 200,000 seeds; Tumbling Mustard, 1,500,000; Shepherd's Purse, 50,000.

The seeds of many weeds are very small and escape notice. A pound of Clover Dodder has 1,841,360 seeds; Common Plantain, 1,814,360 seeds; Lamb's Quarters, 604,786 seeds; Russian Thistle, 266,817 seeds; Wild Mustard, 215,995 seeds; Wild Oats, 25,493 seeds. If 60 pounds of Wheat are planted to the acre, and this Wheat has 2 per cent of Wild Mustard seed, there will be distributed over that acre 388,791 Mustard seeds.

Not only do weeds produce seeds in tremendous numbers, but seeds with an ability to live a long time. The seeds of some weeds, when buried in the soil, may retain their power to germinate for 15 to 30 years. Such is true of the seeds of Tall Pigweed, Black Mustard, Shepherd's Purse, Dock, Yellow Foxtail, Chickweed and others.—*Garden Club of America Bulletin*.

Training Young Men in the Gardening Profession

WILLIAM GRAY

CONSTRUCTIVE criticism is beneficial, for it is in this way all real progress takes place in the world. When we discuss the need of a school for training young gardeners, we are criticising existing methods of training, for if these were satisfactory there would be no need to discuss other plans of training.

Therefore, if the criticism from practical gardeners is of such an extent as to be erroneously called "everlasting knocking of our colleges," there must be some reason for the criticism, and if such criticism is constructive it should be given consideration. Criticism of the college graduate reflects upon the college and its system of education, and going to the root of the matter we are led to believe that the reason for such criticism is the big dose of theory and the small dose of practice that is given the young men at our Agricultural Colleges. Let us define practical and theoretical, and see which is of the most importance.

Practical—capable of applying knowledge or theory to practice.

Theoretical—depending on theory, not practical, speculative.

Practice—dexterity acquired by habit, exercise of a profession. Accepted or proven theory is based upon the best known methods of practice, and therefore is not speculative. The speculative quantity is the theoretical trained man who has yet to prove that he is capable of applying knowledge or theory to practice.

A young man with a fairly good education can become a thoroughly trained gardener by practice alone, but this can not be possible by theoretical study alone. We can therefore assume that practice is of far greater importance than theory, yet there is no doubt that the two combined would turn out more proficient men, and if the importance of practice is greater, the young man should receive more practice than theory.

Our Agricultural Colleges have made progress in remedying this defect in their education, still there is great need for more practical training. The criticism of the practical trained gardeners is directed at the assumption on the part of the college graduate to consider himself competent to fill the executive position of superintendent or head gardener on leaving college, whereas, owing to the lack of much practical training, he is in no position to direct others or to know whether they are doing a thing right or wrong.

That the majority of Agricultural College graduates have been unable to hold such positions for any length of time proves that the criticism is just. A bond of sympathy could be established between the college and the practical man by the faculty impressing upon the young men the importance of rounding out their education by serving for a few years in subordinate positions under thoroughly practical gardeners.

It is open to question whether or not horticulture should be taught in an Agricultural College along with agriculture. Both subjects are of such a broad nature that it would be almost an impossibility to provide the facilities for practical training for both in one institution, and the fact that Agriculture is of more economic importance would tend to the favoring of that science.

Let us consider therefore a proposition to establish a School of Horticulture, the object being to train young

men for all the opportunities that Horticulture presents, *i. e.*, landscape gardeners, private gardeners, market gardeners, fruit growers, florists, nurserymen, foresters, etc. From the foregoing we will assume that practice and theory are going to work hand in hand to get the most efficient results. The school buildings would be of the usual type, presided over by a head professor and his assistants. Young men would be eligible to enter the school at an early age, a high school education not being required for the students would be educated at the school in all subjects that would be helpful to them in their profession and such subjects would be taught only from the standpoint of their relation to horticulture. The grounds around the buildings would be of ample size to afford every facility for the application of the principles of horticulture. A superintendent thoroughly practical would be in charge of the outside departments and under him at the head of each department there should be a practical gardener, expert in the work of the department.

A general plan of development would be mapped out, the different departments being arranged as follows: Landscape Department, consisting of the grounds proper laid out in lawns, drives, walks, flower gardens and borders, planted with trees, shrubbery, and foliage and flowering plants; Vegetable Garden Department, a plot of some extent for the culture of vegetables; Orchard Department, several acres of ground devoted to fruit; Nursery Department, several acres of ground with propagating house and frames for the cultivation of trees, shrubs, and hardy plants; Greenhouse Department, a range of houses for the cultivation of plants, flowers, fruit and vegetables under glass, and plants for the grounds and vegetable garden.

All work pertaining to horticulture would be done by the students under the guidance of the expert head gardener in each department. Lectures by the professors and cultural talks by the superintendent could be delivered wherever the students were at work, the subjects of the lectures and talks correlating with the work at which they were engaged. Thus on pleasant days during Summer the class room study period would be short and more time given to it in Winter or during inclement weather, when outside work would be at a minimum.

The full course would occupy four years. The first two years would be the critical period in the school, for many of the young men would undoubtedly be without experience, but as they became more proficient and had reached their third and fourth year of training many of them could be put in positions of more or less responsibility in the different departments.

The expense of such a proposition would be considerable, but need not present unsurmountable difficulties. The school could be started on a modest plan; the development extending over several years providing students practice in its development. All horticultural interests in the country could get behind such a plan. The grounds could be stocked to a great extent through horticultural organizations. Owners of private estates could be interested in it. Government support might be secured as the economic value to the country of sending out trained men of this kind was recognized.

All this is theory. Is it practicable?

Departments of Foreign Exchange and Book Reviews

EARLY BULB FORCING

OF the many details leading to success in the matter of early bulb-forcing, a timely start and suitable varieties are essential. Early planting is necessary to ensure a healthy root system which will enable the plant to bear the strain presently to be placed upon it, and without which, failure, wholly, or in part, of the crop might be foredoomed from the start. For this there is no substitute; no rushing in at the last moment in the hope of making up for lost time. The bulbous plants I have in mind are Roman Hyacinths, Daffodils and Tulips. Of these three, those last named are invariably the most sparsely rooted, and in their case it may, in a measure, be true to say that other things—*e. g.*, bottom heat and darkness—play an equal part so far as ultimate success is concerned. The root system of the bulbs of the other genera named are stronger and more abundantly produced, that of the Daffodils in particular, and in their case, that of healthy bulbs very considerable. In this connection, root production in these plants, grown, when taken indoors, under entirely foreign conditions, has an important bearing upon the water supply, hence, to the gardener, the information should be appreciated. Of the bulbous rooted subjects under consideration, the Tulip requires the least root-moisture; the other two—Hyacinths and Daffodils—in reason, can hardly be given too much. This, I state with emphasis, having seen the Daffodil ruined in its thousands for lack of moisture alone, or through drought in the soil and an arid atmosphere combined. Under the greenhouse stage in proximity to the hot-water pipes, is no place for this crop, yet I have seen bulbs there, and neglected in the matter of watering for weeks on end. To introduce the plants from the plunging beds out-of-doors to such conditions is ruinous; rushing the plants into considerable warmth from the open is also another common cause of failure with the Daffodil. This, together with growing the plants for ten days over strong bottom heat and withholding water for a like period, are among the ruinous and unpractical methods that I know have been resorted to by some commercial growers in a rather large way of business.

DAFFODILS.

Of the three genera named, the Daffodil is the most impatient of strong heat at the start; a season of preparation—fourteen days or so—of comparative coolness, with moisture, is far better. Heat, indeed, too early applied, not infrequently has a retarding effect upon the crop, apart from which, later, there is an absence of uniform growth and flowering. Hence, from the economic standpoint, seeing the high price of fuel, much might be advanced in favor of the cooler, progressive, and more rational treatment of forcing.

In certain instances, when the forcing of such bulbs was in its infancy and all had to be learnt in connection therewith, some experimenting was necessary. This revealed the absolute stubbornness of certain early and cheap sorts of bulbs, and how they refused to budge when placed in artificial heat. How, too, after two months or so of forcing, when turned outside in disgust in wintry weather to take care of themselves, they flowered at their natural time as though nothing had happened. The value of these experiments lay in finding which were the more responsive ones to forcing and which to-day, so far as I am aware, are still unsurpassed for early work. From the many specimens examined of both Hyacinths and Narcissi, the lack of responsiveness appeared to be no fault of the flower; it was obviously due to the fact that the expansion of the orifice of the neck of the bulbs did not synchronize with the growth elsewhere, with the result that a kind of strangulation was set up; in some instances, the scape was detached from its basal seat with, of course, disastrous results. Cause and effect being clear the lesson was of untold value.

With the season of preparation ended, the house may be closed and a temperature of 45 degrees or 50 degrees maintained. Provided that both fogs and frosts are absent, this may be increased to 55 degrees or so after a space of three weeks. With such deterrents to progress as fog and frost, a lower temperature should be maintained; to do otherwise, would be extreme folly and a useless expenditure of fuel. From now, onwards, there should be no stint of root moisture for all Daffodils. A moist atmosphere up to the time of the opening of the flowers is also important. Given these conditions, the cultivator has at his disposal the essentials to a successful issue. For earliest work *Narcissus obvallaris* (the Tenby Daffodil), *N. Henry Irving*, *N. spurvus*, and the old double-yellow Daffodil (*N. telamonius plenus*) are still unsurpassed, their flowering being much in the order given where all are grown under identical conditions. Closely following these in

blooming are *N. princeps*, *N. Golden Spur*, *N. Victoria* and *N. Excelsior*, which may be regarded as a richer colored Golden Spur. *N. Ard Righ* and *Countess of Annesley* (Irish Daffodils) have both been put forward as first early-forcing sorts from time to time, and it may be true of the first-named, if the bulbs are Irish grown and forced, not otherwise. Those first named are the chief source of supply for the late December and January market; of the others, *N. princeps* is usually the first. Rather than over-force the second earlies, it is better to have a successional batch of the first. Length of stem is thereby secured; a not unimportant asset in these as in other flowers grown for market. What effect the heat of this Summer and early maturing will have upon the forcing of these flowers will be interesting to watch. Thus, it will be seen that but the merest handful of the great and ever-increasing host of *Narcissi* may be regarded as reliable forcing sorts. Potted or boxed in September, their introduction into the cold house during the early days of November might follow, treating them as already advised. *N. paticus ornatus* is something apart, and late November will be soon enough to bring this occasionally unamiable variety indoors. Pursue an even medium course with it till the flower scapes are well in view. It were better to have a full crop by these means than an earlier one with many distorted flowers possessing no market value. Four-inch-deep wooden boxes of uniform size are the best receptacles for the bulbs and occupy the space in the forcing house to a far greater advantage than pots.

HYACINTHS AND TULIPS

Hyacinths and Tulips require both bottom heat and darkness to force them well, differing in these important particulars from the Daffodils. Length of stem and a refined appearance are promoted thereby, assets of no inconsiderable market value. The earliest batches are best grown in a frame within the house; the bottom heat, always under control, being supplied from beneath the bed, consisting of moist cocoanut fiber with a covering, three inches in thickness over all, of the same material. For Roman Hyacinths and Van Thol Tulips, the depth named is ample. For Tulips of naturally taller growth, a depth of six inches would not be too much. By insuring a uniform heat about the tops of the plants, the good results already noted—stem, length, etc.—follow. By covering the frame with damped sacks or mats, heat is conserved and protection against fogs ensured. Here, it may be noted, that Tulips so grown are most sensitive to fog, hence the cultivator should see that the crop is not removed from the bed and darkness until the stems have attained their maximum and the flower buds fully developed. From experience I am assured that the apparently stunted, green tipped, half-developed flower buds of white-flowered sorts too often seen are a direct result of too early removal from the congenial conditions above noted. Its immediate effect upon the crop is a cessation of all growth, hence, the ills named. Usually it is done with the laudable desire of introducing a second batch, though the keen observer will rarely repeat it. The most ludicrous thing in Tulip forcing I ever saw was the early introduction from frames and plunging beds in the open to the greenhouse stages, where they were fully exposed. It concerned some hundreds of pots of the best bedding sorts. With nothing to promote stem growth, the flowers presently expanded on two-inch or three-inch high stems and, sprawling over the pots, presented a strange sight indeed. A bottom heat of 65 degrees at the commencement may be increased to 75 degrees or 80 degrees, in the course of three weeks; the latter warmth will be ample for ordinary purposes. All bulbs forced in frames must be well watered at the start and given time to become dry before covering them with the fiber. The material below the pots should also be well damped. Subsequently, tepid water only should be applied to the plants. Damp the frame daily by spraying with the syringe. The introduction of the Hyacinth and Van Thol Tulips into the heated frames will depend upon demand, though early November usually suffices. For other Tulips, any time during that month or, say, from the middle onwards is suitable. The best Tulips for early forcing are *La Reine*, *Yellow Prince*, *White Hawk* and *King of Yellows*. The first named is probably forced by the million annually, a pure white sort that has also the merit of cheapness. Intelligently forced, this variety and *Yellow Prince* may be had at Christmas with fair weather, and with foot-long stems. The cultivator would be well advised to grow several successional batches of these two varieties.—*The Gardiners' Chronicle* (British).

COLOR ARRANGEMENT IN THE GARDEN

IN the early nineties, when I first turned my attention to gardening, the only serious consideration given to color schemes was that devoted to the planning of Summer beds. But the remembrance of vivid contrasts produced by masses of red Geraniums and blue Lobelias serves to indicate that the art of color arrangement was not in an advanced state. We may therefore regard the science of color planning as practically non-existent in those days. One certainly saw many pleasing color combinations in the perennial border and shrubbery, but these were more the result of accident than forethought. Nowadays the conception of happy harmonies or striking contrasts in the herbaceous border—and, indeed, in any portion of the garden—is regarded as principal rather than secondary considerations. The wise gardener of to-day selects with the utmost care such plants as will most fittingly associate with the natural surroundings. This careful planning of color effects is, of course, the keynote of successful garden building. The guiding factors in the creation of pleasing color combinations are naturally the colors of the flowers and the period of their display. Nobody would attempt to form color schemes without accurate knowledge of these characteristics. To some people the gift of blending colors seems to be a natural one. To others the taste is an acquired one. In either case there are a few guiding principles which might with advantage be borne in mind by those who contemplate laying out new gardens.

Broadly speaking, there are two methods of forming color pictures—namely, by harmonies or by contrasts. There are times when either may be successfully employed; on the other hand, harmony may be the only permissible arrangement. Flower-borders which are always more often seen at close range should, as a general rule, be treated with harmony, while distant effects may with safety be made by striking contrasts. For the most part, I am of the opinion that harmonious effects are more pleasing to the eye. They are certainly more restful. It is quite true that contrasts have a value of their own. They are useful in certain cases in enhancing the color value of many flowers. For instance, the juxtaposition of purple Michaelmas Daisies and Red Hot Pokers seems to compel special admiration, while emphasizing the rich coloration of each species. But a garden is, after all, a place of rest for most of us, and how can restful peace be more felt than in a garden which is filled with the soothing influence of quietly-blended colors.

Whatever scheme be adopted, there should be a sufficient mass of each color to get the true value. The old plan of putting plants about singly is quite inadequate in the formation of color pictures. Bold groups of each subject yield an all-compelling beauty which is not easily attained in borders made up of inconspicuous color patches. There is no doubt that the feeling of rest which seems to pervade many gardens is far more due to the harmonious coloration than to any other influence. The value of color in house decoration obtains increasing recognition. Few people nowadays select their wall-papers without the most careful regard to the aspect of the room, the furniture and carpetings, and the use to which the room is to be put. Why not extend the same thoughtful observance of color value to our gardens? The best teacher we can have in the matter of color effects is Nature. We have only to look around us to find everyday lessons from which first-hand information may be obtained. The grey clouds floating across an azure sky suggest at once a happy combination of grey-foliaged plants with blue Delphiniums or Anchusas. Again, the blending of colors on the wings of certain butterflies or on the feathers of the peacock are quite suggestive of what may be done in the way of flower association. There are, indeed, hosts of examples which may be seen in the country-side and aptly repeated on a smaller scale in the garden. *Gardener Illustrated*

THE USE AND ABUSE OF GARDEN ORNAMENT

THERE is certainly this advantage in a pergola made of natural tree trunks and boughs that it will not clash with any style of building near it, and it can always be well strengthened by almost invisible metal supports. It must be remembered also that a pergola cannot begin anywhere and end nowhere in particular, but should be a definite structure, such as to form a link approach to the main garden from the dwelling house or the approach to a building.

It is difficult to understand why roses and delicate climbers should be given supports heavy enough to carry a Pullman train and why gardens should have been disfigured by the erection of structures resembling an overhead railway. It is quite time that a protest should be made against the vogue for needlessly heavy and clumsy pergolas, which posterity will smile at.

It is also a common error at the erection of the pergola to place these delightful ornaments cannot fitly be placed just anywhere. However much some may dislike the formal garden, such an artificial creation as a fountain seems to demand formal surroundings.

unless perhaps it be a mere jet of water rising from the surface of an informal rocky pool. Yet this is, I think, not free from objection.

Garden statues, again, when exhibited are frequently admired and it is fortunate, perhaps, that their price prevents more finding their way into small suburban gardens. Greek and Roman statuary are quite out of place, unless the mansion and garden surrounding are in the classical style.

Lastly, one too often sees white wood seats placed where their brilliance and luster strive to outshine the white flowers near them, and they become the most prominent feature in the whole garden. The beauty of a stone seat is, that if left to itself, it will soon tone down and merge into the garden picture. It will become a beautiful part of it, if the design has been well chosen, but it will not dominate it.

It is a safe rule to follow, to allow plants and flowers to provide the chief notes of form and color in our gardens and not rely on brightly painted seats and colored awnings unless we are dealing with a garden planned and planted on Japanese lines.—*South African Gardening and Country Life*.

DEPARTMENT OF BOOK REVIEWS

THE MARKET REVIEW NURSERY WORK SERIES, by F. J. Fletcher, F. R. H. S. Benn Brothers, Ltd., London, England.

The name of the publishers, who have brought out a splendid lot of books for gardeners and nurserymen, including some Englishmen's works most highly prized by Americans, is itself a guarantee of the good quality of this series of six very nicely made booklets. The first and the second volumes which have come to hand, are an earnest of worthy treatment to be looked forward to with eagerness. The limited size, for Volume I consists of only 75 pages and Volume II of a few less, bans all expectation of exhaustive completeness; but there is virtue in the clear and painstaking presentation of all fundamental principles which a book making claim to exhaustiveness of topics is too apt to overlook, or to assume as known. Not many genera of plants are treated in Volume I, which is entitled *Glasshouses and the Propagation of Plants*; but the methods found in England to be most successful in the management of greenhouses are detailed clearly; so too the handling of seedlings and cuttings. And it is certainly better to give an exhaustive treatment of a few plants, as is done very satisfactorily, than to attempt to condense the treatment of practically all plants grown commercially under glass; with the methods once mastered the peculiar points of difference in the production of certain plants can readily be ascertained from common printed sources and even by a little experimentation.

Volume II is of the same general character and quality as the preceding. Under the title *Special Glasshouse Crops*, it handles specifically, Tomatoes, Cucumbers, Melons, Grapes, Sweet Peas, Forcing Bulbs, Lifted Chrysanthemums and Catch Crops and their Economic Value. The final chapter of the book, which is given up to the subject named last in the preceding list, is particularly valuable for its suggestions of how to make the most of whatever space is available. But in the reading of this, as is of course the case with foreign books in general, allowances must be made for differences of climate and national customs and preferences.

COUNTRY LIFE BOOKLETS. Country Life, Ltd., London, and Charles Scribner's Sons, New York.

The publishers of this series, whose periodical is *The Gardeners' Chronicle* of London, are in a position to know the leading authorities and successfully to solicit their co-operation. Of the three volumes examined the one, *Sweet Peas*, is the work of Horace J. Wright, F. H. S., First Honorary Secretary of the National Sweet Pea Society; a second *Violas and Pansies*, has been made by Howard H. Crane, F. L. S., author of *The Book of the Pansy, Viola and Violet*, while the third, *Antirrhinums and Pentstemons*, has been written by A. J. MacSelf, one of the directors of the Chalk Hill Nurseries, in which the two plants are specialties. The titles of other booklets, selected from the list of three dozen or more, are *Storing Vegetables and Fruits*, *Bee Keeping*, *Wintering*, *Production*, *Home Production*, *The Dog*, *Billiards*, *How to Know the Birds*, *How to Prune Roses and Fruit Trees*, *The Greenhouse*, *Pot Plants*. These and the other subjects, confined each one to the average of 30 pages composing one of the little and very inexpensive paper-covered volumes, have been dealt with eminently well, if conjecture may be made from a reading of the three specimens. The entire series ought, unquestionably, to be given a place in the library of every country residence and some of the booklets would be of more real serviceability in the management of a city garden than many other books of greater cost.

THE PRESIDENT'S MESSAGE

As president of the National Association of Gardeners, I extend the most hearty wishes for a prosperous, successful and happy New Year to all officers, members, sustaining members, and to all lovers of plants and gardens throughout this great country.

The past year has been one of the most successful in the history of our organization. Indeed, we ought to feel grateful considering the condition of business throughout the country. Not only in this country, but throughout Europe, large estates have been changing owners and this has been the cause of many gardeners changing positions, consequently bringing hardships and difficulties to them. However, the outlook for the current year is much more satisfactory. I am surprised at this early date at the number of calls I have had for efficient and capable gardeners. Employers are very exacting and they only ask for thoroughly trained men. We must not forget the fact that many men in this country made large fortunes during the World War, and these men, in many instances, are procuring large estates and will need gardeners to develop their grounds and gardens. Many of these men are practically ignorant of gardening, consequently it is our duty in such cases to give our very best

assistance and encouragement to develop more gardens throughout the country.

Assistant gardeners are still in meagre supply and there is no prospect of getting many from Europe for some time to come. During this year a great effort will be put forth to evolve a scheme to encourage young men to take up gardening as a profession. In fact, there is now under consideration a plan, which, if carried out, will give better training and encouragement in gardening to young men than they have ever had in this country. The plan is now well under way and members and others interested will in a few weeks be given full details.

Our association is quite young and has many weak spots but with time, members and officers being interested, a great organization for the real benefit of all gardeners will be built up. I believe in local branches and hope to see many more of them throughout the country. At these conferences we can discuss subjects that the members are interested in and also subjects that can be taken up and discussed at the meetings of the annual convention. Members should never forget, when there is an opportunity presented, to say a good word for our association and explain its objects and always be alert for new members of the right kind.

There are many things which we, as true lovers of Nature and the beautiful, should keep constantly protesting against. The bill board nuisance should be protested against until this disgraceful habit is eliminated. The protection of our native plants ought to be of special interest to us. The finest shrub that we know of in the world, *Kalmia latifolia* will be extinct very soon if it is not protected. There are hundreds of other native plants that also need protection. Digging up our native plants by those who ought to know better, and exhibiting them at horticultural exhibitions is another thoughtless way of destroying our native flora. Exhibiting the flowers of our native plants is quite another thing.

I believe if we are to be progressive that the GARDENERS' CHRONICLE OF AMERICA should be a weekly magazine. A gardening paper that is issued only once a month does not and cannot keep up with the times. More space should be given to subjects that would be of interest to the young gardener. I like a fearless paper that will attack all kinds of wrong doing whether they are the doings of gardeners, seedmen or nurserymen. The owners and managers of our trade and garden magazines are so fond of the almighty dollar that they won't print anything that will injure their advertising. An advertiser can't be offended.

We hope that the convention of 1922 which is to be held in Boston in the early part of September will bring out the largest number of members that has attended any of our meetings. There are many points of interest to gardeners in and near Boston. The finest collection of horticultural books in the world is to be seen in the Massachusetts Horticultural Society's Library—the very oldest and the very newest books are to be seen there. Then there is in the Arnold Arboretum the most wonderful collection of hardy trees and shrubs in the world. There are also many old gardens and many modern ones, too, in this vicinity. There are the Concord and Lexington battle grounds where many of the English and Scotch gardeners' ancestors lost their lives by the shrewd strategy of the Yankee farmers. Harvard University has many unique attractions for the gardener, the Blaschka models of glass flowers; Robinson Hall, the finest school of landscape architecture, and its library and other equipment, in this country. Then in the near vicinity is the Longfellow House and garden; the Hunnewell estate at Wellesley where the finest collection of coniferous trees in this country can be seen. Near Boston are the famous Weld Gardens and the Faulkner Farm Gardens where the sculptors' art and the landscape gardeners' work can be seen at their best. To those who are Christian Scientists, the Mother Church which is one of the finest buildings in Boston, and its attractive grounds will be especially interesting. There are hundreds of historical and other interesting things which can only be seen in this vicinity. We are not like the Californians who always talk about the weather and orange groves. We have lots of weather but many other things too numerous to mention in this greeting. I conclude by wishing all gardeners good success with their crops and flowers during the year 1922, and I hope to greet you all in Boston, next September.

ROBERT CAMERON.

PRESIDENT CAMERON'S APPOINTMENTS

President Cameron has appointed the following directors whose term expired on January 1st, to succeed themselves for a term of three years:

George Wilson, Illinois; John F. Huss, Connecticut; Carl N. Fohn, Colorado; James Stuart, New York; William Kleinheintz, Pennsylvania; Edwin Jenkins, Massachusetts; Joseph Tansey, New York; and George Stewart, Massachusetts, to succeed Robert Cameron, whose term expires January 1st, 1923; Alexander Michie, Long Island, to succeed Robert Williamson, deceased, whose term expires January 1st, 1923.

UNPROFESSIONAL ETIQUETTE

Complaints have come to the secretary's office recently of practices on the part of some thoughtless gardeners towards brother gardeners, which have caused loss to the latter, and in one instance, loss to the gardener's family. In each case it has been based on rumors going around that the gardener is giving up his position, to which there has been no foundation, and resulting in numerous applications to the employer, and in return resignations on the part of the gardener. One gardener gave in his resignation on a week's notice, and another for a little more.

Before impairing a fellow gardener's position, every means should be taken to verify such rumors. There truly can be little comfort in being responsible for a man losing his position, and thus bringing misery to his whole family.

GARDENERS' CONFERENCE AT CLEVELAND

A gardeners' conference will be held under the auspices of the members of the association residing in Cleveland and vicinity, at Cleveland during the week of the National Flower Show in that city, March 25 to April 1. The meeting will be held on the second or third day of the show. Full particulars will appear in the next issue of the GARDENERS' CHRONICLE.

A master gardener knows that he receives from his garden no flowers that are unworthy of a place in beauty's bouquet.

Weeds are the only flowers that are not fully understood.

Sins are often virtues in disguise.

Between heaven and hell there is no boundary line.

A cartoon clipped from a penny newspaper may do the soul more good than the most learned sermon.

A pencil's note or a printed paragraph an inch long may open one's eyes to more knowledge than one often finds between the covers of a pretentious book.

To know these truths is to know the pearl that leads to wisdom.—*Selected.*

AMONG THE GARDENERS

Does any member of the association know the present address of Mr. William Puffpaff, formerly with Mrs. C. W. Goodyear, Buffalo, N. Y., and Mr. Melburn, formerly with Mr. Thomas Adams, Bayshore, L. I.? If so, will he please advise the secretary?

Angus G. Ross, who was for many years superintendent of the late Jonathan Thorne estate, Bridgeport, Conn., has accepted a similar position on the estate of S. B. Thorne, Greenwich, Conn.

Thomas Twigg has secured the position of superintendent on the E. F. Luckenbach estate, Port Washington, L. I.

David Watson accepted the position of superintendent to Dr. J. Henry Lancashire, Manchester, Mass.

Archie Campbell secured the position of gardener to J. F. Havemeyer, Ardsley, N. Y.

Robert Finnie has accepted the position of executive foreman of Allegheny Cemetery, Pittsburgh, Pa., under William Falconer, superintendent.

ROBERT BOTTEMLEY

As the GARDENERS' CHRONICLE goes to press, the Secretary has learned of the death of Robert Bottemley, the superintendent of Brush Ridge Farm, New Canaan, Conn. Mr. Bottemley was one of the oldest members of the association.

NEW MEMBERS

The following new members have recently been added to our membership list: Walter T. Thurley, Dalton, Mass.; James Daddio, Westbury, L. I.; A. J. Long, Warrenton, Va.; James F. Pritchett, Great Neck, L. I.; Harry Lindberg, Council Bluffs, Iowa; John Woodger, Scarsdale, N. Y.; Nicholas H. Lean, Aradwan, Mass.

A MESSAGE FROM THE EAST

"Arawa," Rotorua

Residential Hotel, December 10, 1921.

Dear Mr. Ebel:—

Have been in New Zealand a week, and leave on the 15th for Sydney. This is an ideal country for plants and flowers.

One will see growing beautifully in absolutely perfect health in the same beds or borders, specimens of the following: Azaleas, *indica* types, 6 to 10 feet high and camellias 9 to 12 feet, ericas, and even to Cavendish pine. The Forestry Department tells me *Erica pyramidalis gracilis* is spreading all over this district and Daphne is 10 feet across and 4 feet high; also big masses *Hydrangea otaksa* and the French varieties as large as a hay cock, and literally covered with flowers.

The roses are splendid for size and color. I saw the trade rose exhibit of W. E. Lippiatt, of Otahuhu, at Auckland Fair last Saturday. He showed 35 novelties all new for 1921 in his rose exhibit. He lost two sons and a brother in the war and is still going strong. That's the stock we are all proud of. More power to you, Brother Lippiatt.

Had a couple of days with the Government Forestry Department. The fern forests are the dream of a life time. Hope to have the pleasure of telling the growers at Greenwich all about it.

No use telling you about the fishing, as some of the boys would say, "Just a fish story." Honest, we go fishing for trout in a row-boat and take a power scow to bring the catch home.

Splendid agricultural and dairy farming country, and fine horses, cattle, sheep, etc., are here. The people are fine, clean, healthy citizens; and the children are just little kings and queens. I saw some fifteen of them ride in from the farms in one bunch to school on their ponies, one, two or three on a pony, bare back. All were dressed and wearing rubber coats as it was raining. There is a paddock near the school where they turn their ponies loose during school hours. No royalty ever had a better time. Schools and hospitals are free, and are supported by the State. If we can afford to educate our children we ought to be able to afford to take care of their health in sickness and distress.

We left Vancouver on the 12th of November and arrived at Auckland on the 3rd of December, via Honolulu and Luna. It was warm in Luna and for ten days after crossing the Equator. I expect to spend Christmas in Toowoomba, Queensland, with a sister of mine, and after seeing some of Australia, go on to the Philippines and Japan, etc., and then back to the United States by 'Frisco and home about the middle of March.

Well the fly rod is ready, and the boat and scow are waiting. I am off for the Rainbow trout, 4 to 12 pounds.

Regards to all,

Sincerely,

JOHN H. TROY.

I*F you are engaged in the pursuit of horticulture whether for pleasure or for profit you cannot fail to be interested in the Gardeners' Chronicle, for, as you will observe by studying its columns, it is devoted exclusively to the science of floriculture and horticulture.*

LOCAL SOCIETIES

NEWPORT BRANCH

The Newport Branch of the N. A. G. held a meeting December 7, at which Andrew L. Dorward was re-elected Chairman, and Frederic Carter, Secretary for the coming year. It was also voted that future meetings be held at the call of the chairman.

William Gray gave a very interesting account of his visit to the annual convention and of the very enjoyable time he had. The annual report was discussed at some length, some valuable suggestions being offered which are to come up for further discussion at a future meeting.

The Newport Branch feels very encouraged by the organizing of a local branch in Nassau County, also of the proposed one in Boston, and it feels sure others will soon follow. The local branches are going to be the backbone of the association when enough are organized to do effective business, and when the members will take the work of the association more seriously than some do at the present time. We feel the association is making more and more progress every year, and that 1922 will show still more the spirit of co-operation and progressiveness is the New Year wish of the Newport Branch.

FREDERIC CARTER, Sec'y.

TARRYTOWN HORT. SOCIETY

The annual meeting of this Society was held in Masonic Hall, on Dec. 29th, with President J. McDonald and a good number of members present.

One life and four active members were elected. James Scott, John Grant and Edward Kane were appointed judges and awarded E. W. Neubrand's prize for Best Pot Plant to Wm. Graham for a splendid plant of *Begonia melior*.

Election of officers resulted as follows: President, Thos. Wilson; Vice-President, Wm. Graham; Secretary, E. W. Neubrand; Assistant Secretary, E. W. Neubrand, Jr.; Treasurer, John Featherstone; Rep. Secretary, W. G. Weston. James Scott installed the new officers in their respective stations with words of kindness and advice mixed with ready wit and humor, which tend so much to making such events enjoyable and memorable.

The Treasurer's report shows the society to be in excellent condition, financially. The society's dinner will be held January 10th.

W. G. WESTON, Rep. Sec'y.

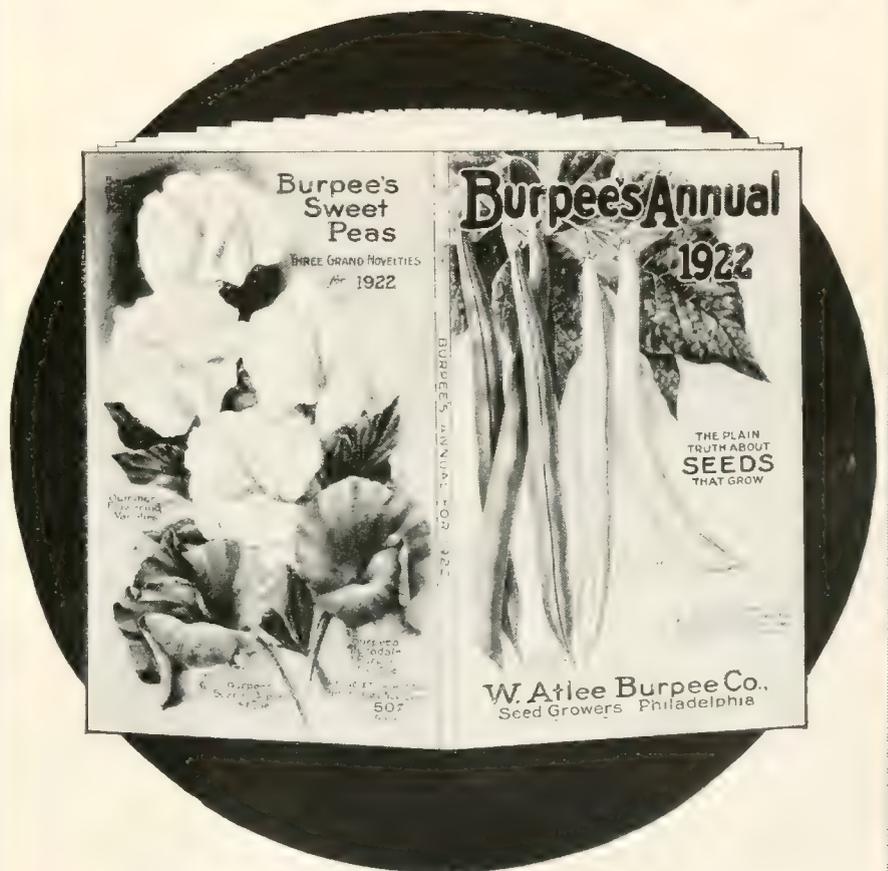

WESTCHESTER AND FAIRFIELD HORT. SOCIETY

This society met in the Knights of Columbus Hall, through invitation, on Tuesday, Dec. 13. As yet we have not secured a permanent meeting place, but this will be taken care of at our next gathering.

The officers for 1922 were elected to serve as follows: President, James Tough; Vice-President, James Linane; Secretary, George Hewitt; Treasurer, James Stuart; Corresponding Secretary, H. Jones; Executive Committee, Robert Wright, Walter Slade, Alex. Gregg, John Rutherford, Edwin Beckett.

Business was suspended and a short silent period asked for by our president as a token of esteem and regret for our brother, Robert Williamson. Through his sudden and unexpected death we have lost one of the oldest, most active, and highly respected members of this organization. He was one of

Burpee's Seeds Grow

BURPEE'S ANNUAL

The Leading American Seed Catalog

Burpee's Annual gives reliable information about Burpee Quality Seeds. It fully describes the best varieties of vegetables and flowers, and more than a hundred Burpee specialties are illustrated in the colors of nature. Burpee's Annual will be mailed to you free. Write for your Annual today.

the few that first formed this society and during its twelve years of existence he has been conspicuous at all times by his untiring efforts in its behalf. He has served in every office giving his best at all times not only for the society but for his fellow gardeners also. His genial disposition added greatly to his popularity and the high standard of integrity evidenced in all his dealings made him a member endeared to us all. He was carried to his last resting place by members of this society, men who belonged to the profession in which his greatest and dearest interests were always centered.

GEORGE HEWITT, Sec'y.

NASSAU CO. HORT. SOCIETY

The annual meeting of this society was held on December 14, in Pembroke Hall, Glen Cove. President Noonan occupied the chair. E. H. Crawford was elected to honorary membership and two petitions for active membership were received. James McDonald, James Michie and James Holway judged the exhibits.

The treasurer's report shows the society to be in a strong and growing position. President Noonan appointed John F. Johnston chairman during election of officers and Messrs. Purchell, Trepass, and Adler acted as tellers. William Milstead was elected President; John Forbes, Vice-President; Ernest J. Brown, Treasurer; Edward Harris, Recording Secretary; Arthur Cook, Corresponding Secretary; William Noonan, trustee for three years.

William Milstead will select his executive committee. J. Everitt, E. Westlake and Ernest Brown will make arrangements for the annual dinner of the society to be held on January 25.

ARTHUR COOK, Cor. Sec'y.

STAMFORD HORT. SOCIETY

Regular monthly meeting of this society was held on Friday, January 6, President Henry Wilde in the chair.

At this meeting the installation of officers took place, and the following are the officers for the coming year: President, Henry Wilde, re-elected; Vice-President, J. Rutherford; Treasurer, A. Pederson; Secretary, O. A. Hunwick; Corresponding Secretary, T. F. Chrystal.

T. F. CHRYSTAL, Cor. Sec'y.

TUXEDO HORT. SOCIETY

The annual meeting of this society was held on Wednesday evening, January 4.

The following were elected as officers for 1922: President, John Livingston; Vice-President, Wm. Ward; Treasurer, Duncan MacGregor; Secretary, James Davidson; Executive committee, David MacIntosh, Joseph Tansey, Charles Davidson, Thomas Lyons, Robert MacClintock.

The reports of the Treasurer and Secretary showed the society to be in good condition.

JAMES DAVIDSON, Sec'y.

SEWICKLEY HORT. SOCIETY

At the last meeting of a very interesting year the above society elected the following officers for the new year: President, Manus Curran; Vice-President, Herman Rapp; Treasurer, W. W. Scott; Secretary, Geo. W. Kirk.

The society is growing in membership, and greater interest is being taken in horticulture by amateurs.

G. W. KIRK, Sec'y.

SEED SERVICE — PLUS

FOR 121 years J. M. Thorburn & Company specialized in high-quality seeds. Their service to the American public, their quality of merchandise, their dependability is well known the country over.

For 85 years James Carter & Company of England has been supplying garden lovers everywhere with "tested" seeds under the label of "Carters Tested Seeds"—seeds selected from strong, vigorous plants, true to type and of the best strains.

We wish to announce to the American garden loving public the consolidation of these two companies. Over two centuries of seed service-ability are now united into a single organization and we are enabled to give you a service never before obtainable in this country.

Through our different sources of supply we are in a position to furnish seed grown in a locality where inbred strength means success to your planting and our tests have eliminated all but the highest grade seed.

CHESNUT HILL PHILADELPHIA

Here and There

THE COCOANUT PALM

On account of its varied products the coconut (*Cocos nucifera*) is the most important of all cultivated palms. It is estimated that the world's output of the two coconut products, copra and coir, before the late war, was 50 per cent greater than that of rubber and only 40 per cent less than that of gold. The coconut is widely cultivated near the sea in all tropical countries where the average temperature is 70° F. and where there is no great variation in temperature between seasons. Owing to the thick fibrous outer covering of the fruit the entire nut will float and retain its power of germination for a considerable time, which no doubt has been a factor in its distribution along seashores. As its nearest relatives are all native of America it is believed, despite its very wide geographical distribution, that the coconut palm is of American origin. However, it is said to be indigenous to the Cocos or Keeling Islands of the Indian Ocean and to have been carried westward in prehistoric times. It was cultivated in Polynesia and Malaya for an edible crop before its discovery by Europeans.

In tropical countries where the coconut is grown practically every part of the tree is used in some form by the natives. The roots are used as a medicine, particularly as an astringent, and are frequently chewed as a substitute for the betel or areca nut. They are also used in basket-making, being interwoven with fiber. The trunk, when mature, develops a very hard external covering which is used in native hut building and is occasionally exported for cabinet work under the name of porcupine wood. It takes a high polish and is recognized by its peculiar ebony-like streaks irregularly disposed over a reddish-brown ground. The young leaves, particularly the leaf bud, is much sought for as a vegetable or salad, and the mature leaves are put to many uses, such as mats, baskets, shingles for native huts, fences, clothing, and ornaments. The leaf-stalks or petioles are made into tool handles and when cut into short lengths and frayed at one end are used as brushes. The midveins of the leaves furnish a strong fiber which is very desirable for basket-making, strainers, and native fishing tackle. The large fibrous triangular-woven sheaths which surround the trunk and the base of the leaf-stalks are cut into various shapes to form mats. The fibrous coverings of the flower spikes, when dried, are used as torches and when twisted and soaked in water are made into coarse rope.

The mature nuts enter into the composition of various native sweetmeats and curries. The water enclosed within the unripe fruit is a cool refreshing drink that is much appreciated in most tropical countries and constitutes the only available drinking water in some of the smaller oceanic islands. Coconut milk is prepared by grating the white meat, mixing it with water and subsequently straining the mixture through cloth, the so-called milk consisting of the oil in suspension with a little mucilage and sugar. It is extensively used in India as a substitute for cow's milk.

The coconut enters into the superstitions of the natives of the Malaya-Polynesia region. Murray tells of a tribe of cannibals, among whom it is not proper for the slaver to partake of his victim, this privilege being reserved for his companions, but he may eat the heart, if during the course of his meal he sits on one coconut and balances himself with his feet on two others.—*G. H. Pring, Missouri Botanical Garden Bulletin.*

The 1922 Ten-Ten Book Is Ready for You

This new Ten-Ten Book has all the good points of last year's with a lot of new ones beside.

Again we've listed the ten best of everything for garden use.

You can make your selections without a lot of fussing through arm-long lists.

Both common and botanical names are given, with just the description and prices you want to know about.

Here is a list of just a few of the headings:

- | | |
|---|---|
| 1. Ten Annual Flowers for Cutting. | 6. Ten Plants for Paved Walks. |
| 2. Ten Annuals for Dry, Sunny Spots. | 7. Ten Shrubs for Hedges and Boundary Planting. |
| 3. Ten Perennial Seeds for Spring Sowing. | 8. Ten Evergreens for Foundation Planting. |
| 4. Ten Hardy Phloxes. | 9. Ten Choice Apples. |
| 5. Ten Plants for Home Decoration. | 10. Ten Choice Peaches. |

Send for your copy of the Ten-Ten Book now; it is free. Then order early.

A THOUGHT FOR EVERY DAY

If you, my friend,—just you and I,—
Should smile instead of worry;
If, as the days and moments fly
Amid life's stress and hurry,
We aim to make our thoughts more kind,
Our hearts and words more tender,
To be to others' faults more blind,
For evil good to render:
Then what a change would come about
In all this dark world's story,
If thus the Christ through us shone out,
Revealing there his glory!

*Frederick M. Steele,
C. S. Sentinel.*

The book of nature is always open Winter and Summer and is always within reach, and the print is legible if we have eyes to read it. But most persons are too preoccupied to have their attention arrested by it.—*John Burroughs* in "Field and Study."

*The Insecticide that
kills plant Lice
of many species.*

The Insecticide of Recognized Merit for Greenhouse and Garden

APHINE is a concentrated material—mixes readily in water—efficient in its action—easily applied—free of the disagreeable odors and features of most insecticides—excellent as a wash for decorative plants.

FOR THE GARDEN—As a remedy against all sap sucking insects infesting flowers, fruits and vegetables APHINE is most effective.

FOR THE GREENHOUSE—Applied at regular intervals (once each week or ten days) APHINE will keep plants in the greenhouse and conservatory free of insect pests.

FUNGINE—For mildew, rust and other blights affecting flowers, fruits and vegetables.

VERMINE—For worms and insects infesting the soil.

Plain Facts About This Ornamental Greenhouse

Why talk of the obvious, why not talk of the possible? The greenhouse is not a mere structure, it is a world of life and growth. It is a world of light and air, of warmth and moisture. It is a world of beauty and utility. It is a world of peace and quiet, of rest and repose. It is a world of health and happiness, of joy and contentment. It is a world of hope and promise, of faith and belief. It is a world of love and affection, of kindness and generosity. It is a world of truth and justice, of honor and integrity. It is a world of wisdom and knowledge, of skill and artistry. It is a world of power and strength, of courage and valor. It is a world of glory and triumph, of success and achievement. It is a world of peace and harmony, of unity and cooperation. It is a world of love and compassion, of mercy and forgiveness. It is a world of hope and faith, of trust and confidence. It is a world of joy and happiness, of peace and contentment. It is a world of life and growth, of beauty and utility. It is a world of peace and quiet, of rest and repose. It is a world of health and happiness, of joy and contentment. It is a world of hope and promise, of faith and belief. It is a world of love and affection, of kindness and generosity. It is a world of truth and justice, of honor and integrity. It is a world of wisdom and knowledge, of skill and artistry. It is a world of power and strength, of courage and valor. It is a world of glory and triumph, of success and achievement. It is a world of peace and harmony, of unity and cooperation. It is a world of love and compassion, of mercy and forgiveness. It is a world of hope and faith, of trust and confidence. It is a world of joy and happiness, of peace and contentment. It is a world of life and growth, of beauty and utility.

The tribute of Herbert E. Belcher to Davey Tree Surgery

175 Windsor Avenue, Buffalo, N. Y.

The Davey Tree Expert Co., Inc.,
 Kent, Ohio

Gentlemen: I am very well pleased with the work done on the trees here. All the trees are doing well. I must add that a more polite and courteous group of men I believe I have never met on a job. They are a credit to your company, and I shall always be glad to recommend them for their fine character as well as their excellent work.

Sincerely yours,

Herbert E. Belcher,

Sup't. J. D. Larkin estate.

Every gardener and estate superintendent has a most important work in the saving of trees under his care. Davey Tree Surgery brings to his aid the highest development of science plus a generation of experience. A careful examination of your trees will be made by appointment.

JUDGE J. T. MAREAN'S INCOMPARABLE DAHLIA CREATIONS
Produced By Himself in His Private Gardens at Green's Farms, Conn.

Introductions for 1922.—

ALL PRIZE WINNERS

HERCULES, decorative; quilled; enormous flower on strong straight stems; blending of tangerine and deep yellow. \$10.

JUDGE ALTON B. PARKER, decorative; fine golden buff; very large flower on strong stiff stem. \$10.

MABEL THATCHER, decorative; fine large pale yellow flower on strong stem. \$10.

MRS. JOSIAH T. MAREAN, peony flowered; perfect; extra large flower on strong wiry stem; beautiful old rose with golden shadings. \$15.

MRS. JOHN T. SCHEEPERS, decorative; very beautiful flower of a canary yellow changing to a soft pink suffusion on outer petals; strong stout stem. \$15.

OVER THERE, decorative; most attractive large flower on very strong stem; of a true self deep salmon color. \$10.

THE BASHFUL GIANT, decorative; the largest flower so far produced; strong stem, on which the flower turns its head slightly; fine apricot with golden shadings. \$10.

THE EMPEROR, decorative; unquestionably the most aristocratic of them all; a maroon of the finest type; very large flower, made up of long flat petals; a magnificent Prize Winner of the highest merit. \$25.

THE MERRY WIDOW, decorative; enormous blooms on stiff short stems, held erect; clear yellow, suffused with a pleasing shade of red but so arranged to make a handsomely colored Dahlia. \$10.

Introductions of 1921, all of which have "made good" and have taken Blue Ribbons at the Shows:

AGNES HAVILAND, decorative; fine rose-pink slightly suffused with yellow. Large flowers on strong stiff stem. \$6.00.

CHARM, decorative; burnt orange shading to yellow; strong wiry stem. \$7.50.

DAKOTA, decorative; shade of flame; enormous flowers on stiff stem. \$6.

E. T. BEDFORD, Hybrid—decorative; purple with silvery shading; exhibited of size 12 inches and over. Long strong stems. \$10.

JUDGE MAREAN, decorative; blending shades of salmon pink, red, orange, yellow and pure gold; large flower on long strong straight stem. \$7.50.

LADY BETTY, decorative; lovely creamy-white, pinkish suffusion; very large, finely formed flower on stiff stem. \$7.50.

LA GROSSE BÊTE, decorative, enormous cerise self color; strong stem. \$7.50.

LE TORÉADOR, decorative; fine lasting exhibition flower; finest crimson shade; strong wiry stem. \$6.00.

MEPHISTOPHELES, Hybrid—decorative; a masterpiece; ruby red, tiny golden points at the very ends of some petals. Now \$15.

MRS. I. DE VER WARNER, decorative; considered the most beautiful in the collection; awarded many First Prizes at flower shows; very large beautifully colored flowers, a shade of soft deep mauve pink; long, strong, wiry stems. \$15.

STOCK OF ALL LIMITED

Prices are for **STRONG BULB DIVISIONS ONLY**; realizing what is often the result of propagation, **NO PLANTS** will be offered. **ONLY** Bulbs from clumps out of Judge Marean's private garden of which the plants **HAVE PROVEN THEIR MERIT**, will be distributed.

All Birds Are NOT Woodpeckers

Style No. 8WB.
Complete with
Bracket, etc.

Price, Postpaid,
in U. S. A.,
\$2.75

SIMPLY because some birds choose the path of least resistance and dwell in abandoned woodpecker nests, all too many birdhouses now offered are built for woodpeckers! To attract the birds you must provide food, water, and shelter! But unless the shelter is congenial, do not expect to hold your friends in feathers!

Educator Log Cabins for Birds and Household Pets

are built along lines based upon intimate expert studies of bird and animal requirements. Roomy, yet warm, easily kept clean because of special construction; they are substantially made to give many years of service to either season's guests or permanent friends.

Every Garden and Bird Lover will find our 32-page Booklet describing the complete line of Educator Log Cabins full of valuable hints how to attract birds and how to hold them. Shows many Cabins "at work" under natural surroundings. A copy of this booklet is gladly sent free on request if you mention G. C.

POTASH-MARL

Nature's Plant Food

UNEXCELLED FOR

CROPS — LAWNS — FLOWERS

A Few Facts:

Potash-Marl-grown potatoes were the largest and finest potatoes in the Exhibit of the Stamford Horticultural Society, and the best crop in Westchester County in 1921.

That Potash-Marl is an Ideal Lawn Dressing is proven by the remarkable results obtained by many Country Estates and Golf Clubs.

"The finest flowers I have ever grown," is a typical expression in letters from many Gardeners who have used Potash-Marl in Greenhouses and Gardens.

We have testimonials to verify the above statements

FEBRUARY, 1922

No. 2

Things and Thoughts of the Garden

MONTAGUE FREE

WE started the last leg of our horticultural pilgrimage in England by boarding a train at Paddington Station for the two hundred mile, non-stop trip to Torquay. The journey westward was not so enjoyable as we had anticipated; for too many others had the impulse to travel by that particular train, and, as most of them got to the station before us we were compelled to spend the greater part of the journey sitting on an angular and squashy suitcase in the corridor. Our anatomy is somewhat elongated and occasioned considerable distress to ourselves, and to exploring passengers in their quest for the dining car. However, by entering the dining car as soon as it was open, and dawdling over luncheon until we were invited to leave to make room for other hungry mortals, a comfortable seat was obtained for part of the trip.

Our main object in visiting the west of England was to call on Mr. R. Irwin Lynch, M. A., V. M. H., formerly curator of the Cambridge Botanic Garden, who for reasons of health has retired from his charge at Cambridge and taken up residence at Torquay.

Our first position was under Mr. Lynch and to him, more than to any other, we owe whatever ability we may have as a gardener.

The pleasure of talking over old times, and the profit gained from discussing horticultural matters with so distinguished an exponent as Mr. Lynch, can readily be imagined. His place in the foremost ranks of eminent horticulturists has been recognized by the bestowal of many honors, including the V. M. H., perhaps the highest and most coveted distinction obtainable in the realm of horticulture. His work in developing the Cambridge garden into one of the foremost botanic gardens of the country caused the University to confer upon him the honorary degree of Master of Arts. All this of course is most gratifying to one of his "old boys."

* * *

It was not until our journeyings brought us to the southwest of England that turf was encountered of a greenness and texture that one associates with the far-famed English lawns. The excellent condition of the lawns in this section was due to the fact that the rainfall of the western part of England is much greater than that in the east and in this year of unparalleled drought the western gardeners were distinctly at an advantage in comparison with those in the east. Doubtless many Americans would be surprised to be told that there is great variety in the climate of such a dinky little island as England, but its

topography is such that there is a vast difference in the amount of rainfall received in the various districts. For example, in one part of the mountains in the county of Cumberland the rainfall is over 150 inches a year. On the west coast, generally, the average rainfall is from 36 to 66 inches per annum, whereas in the eastern counties it ranges from 20 to 30 inches only. This is due to the fact that the high ground on the west intercepts the moisture-laden winds from the Atlantic. Incidentally the average annual rainfall in the vicinity of New York is about 45 inches.

* * *

Torquay was our headquarters for gardening exploration in this section. In the town itself are many features of interest to the gardener, for here the climate is such that it is possible to grow many sub-tropical plants in the open air all the year round. Many of these are to be found planted out along the slope of a steep hill overlooking the bay. Here one may find, growing luxuriantly, the Canary Island date palm, *Phoenix canariensis*. The blue gum of Australia, *Eucalyptus globulus*, also flourishes, reaching a height of 40 feet, and blooms profusely. This species has been planted quite extensively in California where it is said to thrive exceedingly well. *Cordylina australis*, the *Dracena indivisa* of seedsmen, which is widely grown as an ornamental plant for vases in America, is extensively planted, both along the Rock Walk and in the pavilion grounds. The effect that it gives is extremely un-English, and one is reminded of the sub-tropics rather than of so northern a country as England. At Torquay it attains the stature of a tree, and branches and blossoms freely.

One remarkable feature of Torquay is the plants growing on old walls. The species most commonly met with is the red valerian, *Centranthus ruber*. Although it was the tail end of the season when we saw it, it was still attractive in many places and the wealth of old flower stalks gave evidence of its profuse blooming earlier in the season. This is a plant worthy of the attention of American gardeners who are confronted with the necessity of finding material that will grow in poor, dry soil.

There is a remarkable fruiting specimen of *Ficus repens* growing on the walls of St. Matthew's Church at Chelston, a suburb of Torquay. As is well known, the foliage of the adult and fruiting branches of this plant is entirely distinct from that possessed by the young plants when they are clambering over a wall or tree trunk. Under suitable conditions, when the plant has occupied the

space allotted to it, its tendency is to throw out almost at right angles, strong growths which have leaves much larger than those of the creeping form. A similar phenomenon is to be seen in the case of English ivy when growing on walls in England. If neglected it will send out these strong growths which will ultimately flower. The specimen under notice, of *Ficus repens* (or *F. pumila*, to give it its up-to-date title), fills the space between two buttresses of the church and attains a height of over 13 feet.

* * *

The most interesting garden seen in Torquay was that of Mr. Eden Phillpotts, the famous novelist. Here, gathered together in a space not much exceeding an acre, was a collection of interesting plants in such variety as would be almost impossible to find in this country in similar conditions. Not only were the plants interesting themselves, but in many cases their growth was such, favored no doubt by the amiable Torquay climate, as to make one, coming from a section where the Winters are of a more rigorous nature, sigh with envy.

For example there were Buddleias fully 25 feet in height, and a splendid specimen of *Berberidopsis coralina* 20 feet high. This beautiful climbing evergreen is a native of Chile and is hardy only in favorable sections even in England. The leaves, two or three inches long, are of a beautiful dark green, and somewhat spiny along the margins. Its small, globular, crimson flowers are abundantly produced on long pedicels in leafy racemes.

Here, too, the climbing Butcher's broom, *Semele androgyna*, from the Canary Islands, was thriving vigorously out of doors. This is one of the most handsome of vines and imparts a curiously tropical appearance in any garden in which it may be grown. It is usually grown as a greenhouse plant and is valuable for this purpose when room can be afforded it. Its small, rather inconspicuous flowers are produced on the margins of the leaf-like branches, in this respect being comparable to the smilax of the florist.

This garden is fully described in a vastly entertaining and whimsical fashion in Mr. Phillpotts's book "My Garden." In his introduction he states that he grows over 1000 different genera and this, be it remarked, in a space of about one acre. It is perhaps this tendency of the amateur gardener in England to grow collections of as many species and varieties of plants as he possibly can that serves much to distinguish him from his confrere in this country. Everywhere throughout the whole of England one may find small gardens, containing a wonderful variety of plants lovingly tended, in part at least, by their owners. It is partly made possible to grow such a large number because of the hold that rock gardening has on the hearts of the English gardeners. The plants used for this purpose, in many cases, are so diminutive that an enormous number of species may be grown on a relatively small area.

In this connection, it may be worth while to again raise the question as to whether more pleasure is obtained from a garden having a great variety of plant material, or from one where the garden picture is all important and made with the use of as small a variety of material as possible. Those who look on the garden as a purely artistic affair are always prone to depreciate the use of a large number of species. This applies in England as well as in this country. We will admit the fact that it is impossible to obtain such truly artistic results when the aim of the gardener is to maintain a large collection of plants. Yet, does not a garden made on the latter principle, assuming of course that the plants are spaced with as much regard to artistic consideration as possible under the circumstances, present to the plant lover a greater variety of

interesting features throughout the year than one designed by a landscape artist who ignores the intrinsic interest that plants in themselves possess, and has no other purpose in view than that of creating a beautiful composition?

The inevitable rock garden was of course in evidence in Mr. Phillpotts's garden but in this case a distinct departure from the usually accepted type was noticed. It might perhaps be described as a "formal" rock garden—formal in the sense that no attempt whatever is made to simulate natural surroundings. Its top is bounded by the straight line of a terrace and its bottom by a similar straight line, parallel to the former, of a gravel walk. The front of the rock garden is raised about two feet above the level of the walk, extends backwards about eight feet, rising to a height of five feet, and covering what would normally be the ordinary terrace slope. The rocks are arranged as naturally as possible and the "pockets" are planted with a varied and interesting collection of alpine and other plants. The dainty wild Cyclamens were thriving satisfactorily here, and also the rare *Erinacea pungens*, a dwarf shrub with violet-blue papilionaceous flowers. *Retinispora Sanderi* (*Chamaecyparis obtusa*, var. *ericoides*), one of the most charming forms in this valuable genus, here proved its fitness as a rock garden evergreen. The quaint and column-like *Juniperus communis hibernica*, was represented in several perfect specimens.

A rock garden of this type may contain suggestions for those who are faced with the problem of maintaining a suitable growth of grass on a terraced slope. In those cases where the slope is so steep as to make it difficult to maintain grass in good condition, it might be worth while to consider facing the slope with rocks and planting it with suitable material. This would be specially serviceable in a small garden where room was unavailable elsewhere for the growth of alpine and rock plants.

It may be mentioned, by the way, that the printed page of "My Garden" presents a strange appearance to those accustomed to orthodox gardening publications, as Mr. Phillpotts for the most part dispenses with the use of capitals for the initial letter of the generic names of the plants. In the case of the specific names, however, he is usually quite orthodox and, in consequence, throughout the book we come upon names written as follows: *geranium Lancastriense*, *bambusa Fortunei*, *fritillaria Sewerzowii*. Whether Mr. Phillpotts is establishing a precedent of his own in this case, or whether he is simply following someone else, we do not know. The Zoologists, in their code of nomenclature, have eliminated the use of capitals in the case of specific names, but we have never heard of anyone dispensing with them for the initial letter of generic names.

This hurried trip into Devon was sufficient to indicate why this county received the sobriquet "glorious Devon." The richness of its agricultural districts, the beauty of its scenery, and the flavor of the far-famed Devonshire cream, was sufficient to prove, to us at least, that the native Devonians are not too boastful in using the adjective "glorious" in describing their county. One soul-satisfying trip was made by automobile over Hay Tor on Dartmoor. On the moor, usually associated with grey granite rocks, were immense patches of golden gorse and purple heather intermixed which provided a picture that was not surpassed in any of the gardens that we had the privilege of visiting.

It was interesting a day or two later to compare in our mind's eye the character of the vegetation that one sees in these upland, moorland regions with that to be found on the chalk downs that, in a large part, make up

(Continued on page 50)

Funkia—Plantain Lily

RICHARD ROTHE

FUNKIA—syns. *Hosta*, *Sansurea*—the plantain lily is a hardy herbaceous genus of the large order *Liliaceae*. Most of the garden species of funkias are well known and easily obtainable, but as to their wide scope for effective employment many of us have only a vague idea. Planted upon a border, sunny throughout the whole day, occupied by strikingly free flowering perennials and annuals, they are apt to prove disappointing. Their spikes of white and lavender bell-shaped blossoms, under the given condition, do not conspicuously augment the vividness of color arrays and, throughout the Middle Atlantic and Southern States, the foliage does not always endure the full force of the mid-Summer sun without injury. However, it is usually the reverse in semi-shady situations or in positions with full sunlight limited to morning and evening hours. Then, in well-enriched and deeply dug soil plantain lilies are sure to develop a captivating ornamentality in perfect foliage and, during mid-Summer, a very acceptable display of

ovata—noteworthy *ovata albomarginata* and *aurca variegata*. The latter is also found listed under the name *Japonica aurea variegata*. Unquestionably the most stately of all is the true *Funkia Sieboldiana*, producing enormous

Funkia lanceolata albo marginata

flowers. Funkias are one of the few dependable items for solving the always more or less difficult problem of establishing a permanent growth on narrow borders running along northern housefronts. If not neglected in watering, the *lanccolata* and *ovata* types even hold out well and look presentable under awnings. When arranging shore-plantations of lake and pond, or, when engaged in brookline gardening we find especially the large robust growing species simply indispensable. Growing in the full sunlight near the water line the foliage rarely ever suffers by reason of excessive heat.

Funkia subcordata grandiflora, a species from Japan, with light green, heart-shaped large foliage and, during mid-Summer, glistening white fragrant flowers, is a universal garden favorite of long standing. The chief attractions of *Funkia Fortunei* are the steel-blue medium sized foliage and light lilac racemes on stems not extending much over the leaves. *Funkia lanceolata*, with long narrow green foliage, is the freest flowering plantain lily, its numerous lavender blue bells being borne on long graceful stems well above the plant. *Funkia ovata*, syn. *caerulea*, distinguished by broad green foliage and pale lilac spikes is one of the best for placing near the water-line. Strikingly beautiful are the variegated forms of

Funkia subcordata grandiflora

steel-blue leaves of tropical luxuriance. For perfect development this species needs a rich sandy loam and an open moderately moist situation. *Funkia minor alba* is a wavy green leaved, smaller growing type, producing long-stemmed white flowers, which, like those of *lanccolata*, are useful for cutting. Of a number of handsomely variegated forms I mention *Funkia robusta elegans variegata*, *lanccolata albo marginata*, *viridis* "Thomas Hogg" and the well known *undulata media picta* frequently used for edging purposes.

Funkia ovata, syn. caerulea

Funkias are best propagated by division early in Spring. They may be also raised from seeds sown in cold frames. Seedlings of variegated forms come true to only a small percentage. It requires from two to three years' cultivation of seedlings before obtaining stock of trade size. Winter protection is required only in northern States.

The Love of Flowers

BERTHA BERBERT-HAMMOND

How beautiful is a flower!
It is like the soul of a child
Set free and growing wild
In the sunshine and the shower.

So fragrant, so fair, so true!
Of the spirit's texture spun,
It smiles with the smiling sun,
And it weeps with the weeping dew.

God loves it—and why not we?
'Tis a face with a soul a-shine,
'Tis a thought of the mind Divine,
'Tis a hint of the life to be.

AS flowers are one of Nature's choicest and most beautiful gifts to mankind, and appear almost human in some of their characteristics, it is quite natural for those who know flowers to entertain a sort of feeling of friendship and warm affection for them. An admiration for these "stars that on earth's firmament do shine" is enshrined in the heart of every lover of the beautiful, and fortunately, it is no longer considered effeminate for our boys and men to display their love and appreciation of flowers.

Many of the European nations have been in advance of us in floral appreciation. Concrete evidence of the appreciation and love of flowers is found in Japan in the almost universal use of names of flowers in the naming of the daughters of the nation and in the designation of their festivals and of certain parts of the year. The Japanese words for cherry-blossom and for chrysanthemum are commonly used as names for girls, and plum and cherry blossom time are observed in the Spring and maple-leaf and chrysanthemum season in the Autumn.

The educational and ethical value of a love of flowers cannot be doubted. The appreciation of the miracle of growing things, and the love of the beautiful instilled into the receptive mind of a child will almost invariably exert an influence that will tend to develop the finer side of the character. As the love of flowers seems innate in a child, it is necessary only to encourage and stimulate this natural tendency and direct and guide the enthusiasm until an intelligent and permanent interest may be established, one that will foster the best development of the individual. With a set of garden tools, carefully chosen in regard to their suitability and adaptation to the size and strength of the child, there is no exercise that is likely to prove more healthful, and fascinating than a moderate amount of digging and delving in the ground. Some persons claim that this nearness to Mother Earth, and the

actual contact of the hands with the soil, exerts a soothing effect on the nerves that is almost magical, and that the transmission of vital currents is effected from the humus in the soil to the human body. John Dryden alludes to the potentialities of outdoor exercise in the following stanza:

Better to hunt in fields for health unbought
Than fee the doctor for a nauseous draught.
The wise for cure on exercise depend;
God never made His work for man to mend.

The constant association with the soil and growing things will leave a mark that is not readily effaced. In her book entitled "Freckles," Gene Stratton-Porter says with truth: "Nature can be trusted to work her own miracle in the heart of any man whose daily task keeps him alone among her sights, sounds, and silences." Those outdoor workers who have labored understandingly and in harmony with Nature, have come to believe that there is a tangible reciprocity between the skilled gardener, the soil and the plant kingdom that gives ample evidence of a responsive higher power, without which the miracles of field and garden would not be possible. We may dig the soil, plant the seed, but without the co-operation of that great and beneficent power, which pervades the universe, our labors would be in vain.

There is something in the composition of normal mankind that demands communion with the outdoors. For centuries man has taken enjoyment and comfort in "green growing things." Dion Clayton Calthrop says: "To garden is part of every man's philosophy. To sow the seeds, to watch the tender shoots come out and brave the light and rain, to see the buds lift up their heads, and then to catch one's breath as the flowers open and display their precious colors, living, breathing jewels, is enough to live for."

Even when grown for pleasure only, flowers have and hold an important place in the economy of life. They exert an uplifting and refining influence that is within reach of thousands of persons who by circumstances are denied the refinements and the æsthetic joys of good music and fine paintings. That person who has in his heart an unaffected love for flowers, has within himself an unfailing source of pleasure and comfort and a capacity for a keen appreciation of the higher things of life. As F. W. Burbridge writes: "Devotion to Flora as a queen among us is as yet a living truth, and among or around the hearts of all true gardeners there is woven a thread of twisted gold."

A Famous Roof Garden

GEORGE CECIL

ALTHOUGH a roof-garden is not an uncommon thing, one which includes fruit and vegetables, in addition to the usual shrubs and flowers, is a novelty. A garden of this description is to be found in Paris—located on the leaden roof of the Louvre.

Seventy-one years ago the chief custodian of the Louvre leads pined for some means whereby he might

utilize his leisure, and, at the same time, beautify the large expanse of flat roof in his charge. One fine day the *plombier en chef* was struck by the idea to convert the leads over the Colonnade into a roof garden. "Figure to yourself," said he to a sympathetic friend, "the space is here, the blessed sun shines in abundance, and I have water to spare. Why, then, should I not construct a

roof garden which besides being the joy and pride of our *belle France*, will become a monument to French industry for all time?" At first the scheme hung fire, the powers-that-be, from whom permission had to be obtained, objecting strongly to the innovation. Not, in fact, till yards of red tape had been expended upon the tying-up of a voluminous correspondence dealing with the subject and covering a lengthy period, did the guardian of the leads receive a favorable reply. But, even then, all sorts of restrictions were imposed upon him, and only when he had undertaken to refrain from laying down earth on the sanctified roof was the desired permission finally accorded.

VIOLETS AND CACTI

Commencing in a small way, the amateur gardener first turned his attention to shrubs, planting them in tubs. Shrubs, however, afforded little scope, even though much success was obtained with flowering varieties, and the industrious plumber be-thought himself of flowers. A number of long, wide boxes were procured, and in them the proud owner of the garden reared Pelargoniums, Violets, Primroses, half a dozen different kinds of Carnations, Sweet Peas, Sunflowers, Tiger Lilies, and so forth. Rose bushes also repaid the loving care bestowed upon them, while the Chrysanthemum, finding the vast depth of the boxes suitable to their particular needs, flourished exceedingly. Even the *Cacti*, imported from exotic Mediterranean shores, took root, thus adding to the interest of the "*joli jardin aérien tout riant*," as George Cain has so aptly described it in his delightful *Nouvelles Promenades dans Paris*.

AN ORCHARD IN THE AIR

Having made the most of shrubs and flowers, the excellent plumber-gardener determined to embark upon a tiny orchard. So, ordering more boxes, he planted in them nursing fruit-trees which, alas! at first refused to bloom. Indeed, not for some seasons could so much as a single modest bud be seen, and the *propriétaire* of the ungrateful trees was depressed beyond words. But one never-to-be-forgotten Sunday in Spring the saddened plumber-in-chief woke to find the blossoms bursting through their coverings, and in due course the Cherries, Pears and Apples ripened. For the past few years the orchard has done all that could be expected of it. In fact, several kinds of eating and cooking apples are grown upon the roof of the Louvre, each being an admirable specimen of its kind.

A VINERY

First the Apple, then the Vine. Experiments were made, and for some time the grower drained the cup of disappointment to its dregs. Eventually, however, he hit upon the right sort of Vine, and his table was laden with grapes cultivated on the premises. In moments of confidence the present *plombier-in-chef* admits that the fruit lacks flavor; but upon ordinary occasions honest pride reduces their acidity. Of late, attempts have been made to induce Peaches, Apricots, Greengages, Plums and Figs to grow, and with disappointing results.

"LEGUMES A CHOIX"

After the roof-garden had been in existence for some years the plumber, prior to retiring from the official position which he had so long adorned, determined to hand down a kitchen-garden to the custodian appointed to succeed him. Having obtained permission from the authorities to extend the scope of his activities, he ordered more boxes, and before many moons had waxed and waned, Black, Red and White Currants, Strawberries and Raspberries, which usually require even more fresh air than a roof-garden affords, greeted the aged gardener's enchanted gaze. Lettuces thrive there; Peas al-

most sprout for the mere asking; and a miniature Asparagus-bed has repaid the attention bestowed upon it.

HEARTS OF FLINT

So succulent is the Louvre asparagus that, at the time of his departure, the gardener-plumber petitioned the Government to allow him an additional roof-space in which to lay down a second Asparagus-bed or, rather box. But the flinty-hearted authorities declined to oblige their old servant though they consoled him with a welcome pension. The plumber, however, did not live long to enjoy it. His thoughts ever were of the forbidden Asparagus.

THE LATE JUDGE MAREAN

THE passing of Supreme Court Justice Josiah T. Marean, while he was sojourning in Winter Park, Florida, has brought to a large number of persons in all parts of the country a keen sense of bereavement. Many who had not come within the sphere of his gentle and gracious personality, yet knew and felt the force of the

Josiah T. Marean

happy philosophy which ruled his life, feel a keen sense of loss.

By his going the horticultural world has lost a commanding power, for in his chosen field the Judge had no peer. Always a lover of flowers and out-of-doors, the Judge had for the past fifteen years devoted his knowledge and skill exclusively to the glorification of the Dahlia. In his lovely private gardens at "Daybreak," Green's Farms, Connecticut, he has worked patiently, ardently, but with sure and discriminating touch to bring forth every latent beauty of this splendid flower.

The triumphant results are known to all the flower-loving world. Almost it has seemed that among his tools in the "green workshop" at "Daybreak" there must have been a magician's wand, for surely magic was wrought—miracles of color and form, and such perfection of finish as has never before been even dimly approached in the development of the Dahlia. Each year fresh wonders were accomplished to the astonishment and delight of an evergrowing audience of admirers; each year it seemed possible for the tranquil worker to transcend perfection.

The Vital Relation of Trees to Human Life and Wild Life

HON. MARTIN L. DAVEY

YOU know, we emphasize the word "freedom" here which means that we do as we please; "every man for himself and the devil take the hindmost." We started out, then, to cut a pathway for civilization across the land of freedom, and in doing so we have succeeded to a large extent in unbalancing the whole scheme of Nature. The trees, as individuals and in groups, are essential to all other forms of life. The bird life is absolutely indispensable for the protection of your trees, and those two things together, linked up with other forms of life, make the essential background for human life.

You know the average person does not seem to realize that the tree is a living thing, really alive. Oh, I suppose when you remind a man of the fact that it is alive, he will say "Yes," but he doesn't realize that it is really a living organism. It has a breathing apparatus and digestive organs; it has a circulation; it has sexual processes.

The tree breathes through its leaves, chiefly; the under side of the leaf is a mass of small openings, myriads of them, into which the air penetrates and gives up its carbon dioxide to be combined with the other food elements that are already in the leaf, having been brought up from the roots, and the oxygen is thrown off again for the benefit of man. It is true that this breathing process does not follow the principle of the bellows as in the human lungs, but it is just as real breathing as occurs in any other form of life.

Then the tree has a circulation, just as truly as you and I have. Away down under the ground the little roots gather up mineral elements in solution; that is carried up in the sapwood all the way to the leaves and there undergoes the chemical change which makes it tree food. But in order that you can get this as a picture, I will ask you to imagine you are looking at the top of a stump, the cross-section of a tree. Right in the center you see the pith and around that succeeding layers of wood, each representing a year's growth. Originally, each of these layers in its turn was sapwood and served the purpose of a sap carrier. As it fulfilled that purpose and more layers were added, it became more and more dormant, so that in a large tree all these cells near the center are practically dormant, and as you go outward toward the bark you find the wood more and more active as a sap carrier. The last few layers just inside the bark are the most active; it is there where most of the sap goes up. The sap is pumped up from down underneath the soil and carried all the way up to the leaves, irrespective of the height of the tree—sometimes one hundred feet, sometimes one hundred and fifty feet or more—there it is transformed, digested. The mineral elements that were taken up in solution are combined by a wonderful process with the carbon that is extracted from the air, and that is all done in the leaf.

The leaf is probably the most wonderful factory that ever existed—more wonderful than any factory that man creates. It is there in the leaf that all food is created, food for man and food for vegetation. In the leaf, under the influence of sunlight, this digestive process takes place which creates the food that makes possible the continuity of all life.

Everything we eat, everything we wear, is manufactured in the leaves of vegetation. It is impossible for man to take into his system directly any mineral elements other than water and salt, and relatively small quantities of those; all others must first pass through the leaves of

vegetation and be transformed into organic substances. Thus we find that the leaf, speaking of vegetation generally, is the one and only connecting link between the organic and the inorganic worlds. And the great God who created the world and the life that inhabits it, made of the lowly leaf the greatest and most wonderful instrumentality of that life.

I have told you about the tree's breathing and its circulation. I have tried to describe, in a way, its digestive process, and now I want to tell you just a little about its sexual processes. In all life there are two fundamental principles; one is self-preservation and the other is reproduction. All living things must follow both of these principles and be governed by them. This is true of the tree as it is of other forms of life. The tree has its sexual organs in the flowers just as real and just as beautiful as in other living things. The male and the female exist as positive factors, sometimes in the same flower, sometimes in different flowers on the same tree. Sometimes you find the flowers of one tree all male or all female. The pollen is created in the male parts, is carried largely by the winds to the female organs, and there the wonderful relation takes place which carries the life on from one generation to another—a wonderful and a beautiful process. And thus we see that although the tree lacks the power of locomotion, though it has no intelligence and no nervous system, in all the other chemical principles it is just as truly alive as man himself.

Another very important phase of the tree question is reforestation. It is an aspect of the matter that comes, I know, very close to your hearts, as it does to my own, because it is bound up closely with your particular problems. I must say that anyone who is solid on the idea of reforestation is bound to be solid on the idea of protecting wild life; and having given some study to the subject I must confess that I am solid on the desirability of the passing of the Public Shooting Ground—Game Refuge Bill. I wish that I were now in Congress so that I might help along this worthy project.

In order to make you understand that these statements are not the result of my imagination and that they do not follow the principle that "the wish is father to the thought," I am going to read to you just briefly from the report of the United States Forest Service to the Senate, published about the first of June, 1920. This was in response to a Senate resolution:

"The outstanding facts reported by the Forest Service are:

"1. That three-fifths of the original timber of the United States is gone and that we are using timber four times as fast as we are growing it. The forests remaining are so localized as greatly to reduce their national utility. The bulk of the population and manufacturing industries of the United States are dependent upon distant supplies of timber as the result of the depletion of the principal forest areas east of the great plains.

"2. That the depletion of timber is not the sole cause of the recent high prices of forest products, but is an important contributing cause whose effects will increase steadily as depletion continues.

"3. That the fundamental problem is to increase the production of timber by stopping forest devastation. The virgin forests of the United States covered 822,000,000 acres; that are now shrunk to one-sixth of that area. All classes of forest land, including culled, burned, and

cut-over areas, now aggregate 463,000,000 acres, or a little more than one-half of our original forest.

Including everything, good, bad, and indifferent,

"Of the forest land remaining and unutilized for farming or any other purpose, approximately 81,000,000 acres have been so severely cut and burned as to become an unproductive waste. The area—"

Think of it—this area that is wholly useless,

"—is equivalent to the combined forests of Germany, Denmark, Holland, Belgium, France, Switzerland, Spain, and Portugal. Upon an enormous additional area the growth of timber is so small in amount or of such inferior character that its economic value is negligible."

Some three hundred years ago there came to the eastern shores of this country a band of pilgrims, and they found what was then the greatest natural wealth, probably, in the world—land covered with a perfectly wonderful growth of trees. Captain John Smith sent back word from Virginia that he had discovered a land of inexhaustible fertility, and so it appeared. But now, less than three hundred years later, we find that thousands of acres in Virginia can be bought almost for a song because that which had been considered inexhaustible is gone—the fertility of the land has been destroyed. On the other rock-bound coast of New England the scene that greeted the eyes of the Pilgrims no longer exists. Three-quarters of the original forest area of New England is gone; half the remaining timber is in the State of Maine. This great section that was so richly endowed with natural wealth, so abundantly provided for, has now reached the point where it imports something like 30 per cent of its consumption, and is rapidly approaching the stage where it will import the major portion of that which it consumes.

The great state of New York some fifty years ago became the greatest producer of lumber in the Union; today it produces not more than one-tenth of its consumption, to be exact, thirty broad feet per capita as against a consumption of three hundred board feet. Then the tide moved to Pennsylvania, and Penn's woods became the greatest producer of lumber following New York. Today its production is less than enough for the Pittsburgh district alone—about 20 per cent of its consumption.

But that is not all the sad story of Pennsylvania. I wonder how many of you have taken a daylight ride across the Alleghenics. Those who have done so must have been shocked at the sight of miles upon miles of hills which have been absolutely robbed of their foliage. And that is not all. While the forests cover the lands the rains come down, percolate through the loose, porous soil into the subsoil, and from there find their way to the springs and thence to the little streams and rivers. It is the network of roots of vegetation in the loose, porous, fertile soil that hold the water in check and gives it continuity—and those who have studied this problem know that the question of water supply is tied up in the whole problem of the protection of the forests.

Then, the reckless methods of the lumbermen are employed and the trees are swept away—oh, so thoughtlessly. I sat with a gentleman yesterday afternoon who described some of the methods he himself had employed, and it almost made me heart sick as he told of how the little trees down to four inches in diameter were cut and the branches left behind, causing forest fires which destroy vegetation and also destroy the very means of holding the soil in place. When this has happened and your rains come down they wash the fertile soil into the streams and into the ocean, soil that it took Nature hundreds of years to produce—all because of the prodigal waste and recklessness of mankind.

We find that the tide moved up into the Great Lake States, where thirty or forty years ago there was such a wealth of timber that people said it could never be cut away—that it was inexhaustible. The original supply in the Lake States—Michigan, Wisconsin and Minnesota—was estimated to be 350,000,000,000 board feet. That has now been reduced to 8,000,000,000 board feet—from three hundred and fifty to eight billion. It is almost gone, including the great white pine that made that country famous.

And then the tide moved into the South Atlantic and the Gulf States, and that vast expanse of wonderful soft woods, the yellow pine, is three-fourths gone; our government estimates that it will be exhausted commercially in from fifteen to eighteen years. The section from which I come, Ohio, Indiana and Illinois, has almost ceased to be a factor in the production of lumber.

There still remains a considerable quantity in the south Appalachian States, but it is estimated by the government that that vast supply of hardwoods will be gone in from fifteen to twenty years. Then, we still have one remaining stand in the southern Mississippi valley, including the cypress; and that, it is estimated, will be gone in about twenty years.

There remain, in this great land of freedom and opportunity, the forest areas on the Pacific coast, in Washington, Oregon, California, northern Arizona and New Mexico, Colorado, Utah, Wyoming and Montana.

When you consider the immense figures, it looks as though these areas were inexhaustible, but every time you exhaust one territory you lay a heavier burden on the next; and thus your government has arrived at the conclusion that these vast quantities of timber on the west coast will be exhausted in about thirty or forty years.

So that we face a problem of forest destruction with all its attendant ills; and I say to those who are interested in wild life—if you forests go, your game and fish go with it. If wise measures are taken to protect the game, they will be taken to protect the forest; and if wise measures are taken to protect the forest they will be taken to protect the game—the two are linked up inseparably.

If I were to offer a solution for the problem, if I had this job to do myself, there are two things I would set about to accomplish. First, I would put all lumbering under government supervision; and I say that as one who hates the idea of government interference in business probably as much as anyone. But I would take it as the lesser of two evils.

I would put all lumbering from now on under the control of the government and under the strictest possible supervision and regulation so that these wasteful methods I have referred to cannot be continued, so that we may be able to protect what we have until we can grow more.

Then I would do another thing that perhaps would not be quite so popular in these days of taxes; still, we have so many taxes now that we are used to it. I would put a tax of one dollar per thousand feet on all lumber cut from now on and every dollar of that money I would put into reforestation.

In other words, we may talk about this question as much as we like, but unless we get down to some concrete proposal, some definite method of procedure, we shall never solve the problem or successfully meet its attendant difficulties. We must get some kind of action, and that without delay.

One more thing I want to say, and this in order to emphasize the importance of the question as bearing upon the future of our country. It was not so many years ago when China had as wonderful a covering of trees as we have now.

It is not so many years, either, since China cut those trees away and burned over the ground; and today there are frequent appeals from China for help. Famine stalks over the land; they have one crop in seven years, and at the other times they are not able to produce it. The destruction of their forests has carried with it, to a large extent, the destruction of the productivity of their land. Over those vast stretches its fertility is gone; and it is impossible for China to reclaim herself until she rebuilds her forests and grows them again to some size.

In the meantime, however, China has become and will continue to be a land of perpetual famine. And the very process that took place in that sad country is going on

here; yet we are doing nothing of any serious consequence to stop it.

So my plea to you, as it is to all whom I carry this message, is that we do something now while yet there is time; so that we may avert in America the destruction that has overwhelmed that vast country of the East.

We in this land of freedom who have boasted so long of our wealth, our inexhaustible resources; we who have inherited so much from the past, owe a debt to our children and our children's children. We owe it to them so to act that when they come into their own they will not point back to us with the finger of scorn because of our prodigal waste.—*Bulletin of American Game Protection Association.*

The Nephrolepis Chart

R. C. BENEDICT

THE illustration below shows the Nephrolepis chart which was exhibited at the Boston Fern Show in connection with the Brooklyn Botanic Garden fern collection. The chart represents one of the results of a study of these forms which has been carried on at the Brooklyn Garden for the last six or seven years.

relationship as indicated on the chart are numerous varieties of *Nephrolepis*, about 75 different kinds. Practically all the forms represented on the chart will be maintained constantly in this house, together with a collection of English varieties of Boston Fern and other forms of interest.

In connection with the chart, there is framed the following statement:

"The ferns in this house include practically all the best kinds for use as house plants. On the left bench are the kinds commonly sold as 'table ferns' because so many are raised and sold to fill fern dishes. Many of them are useful also as larger pot plants, and can be grown by anyone who can raise other house plants successfully. Even in ordinary apartment conditions, with dry air, drafts, too much heat, too little light, fumes from illuminating gas, irregular or too much water, they may be expected to remain decorative for weeks, sometimes months.

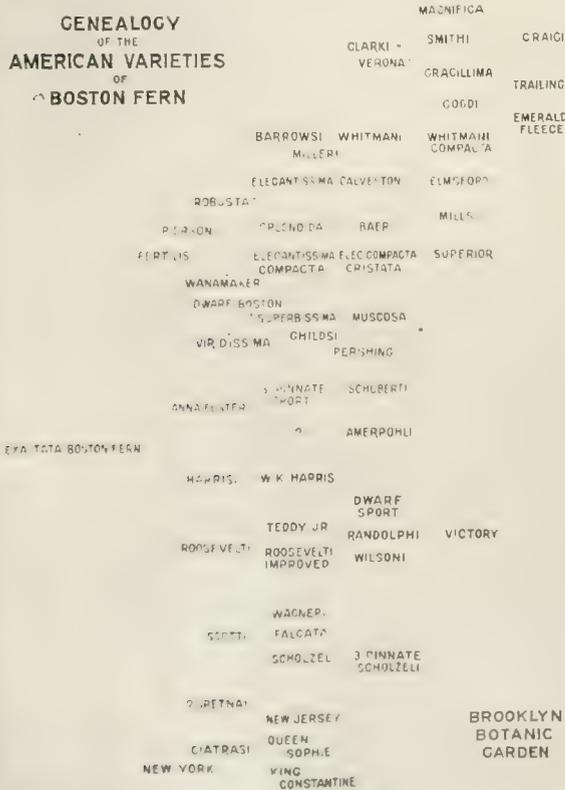

"The ferns in the center and at the right are also useful house plants. They are of further interest because they illustrate the evolution of new varieties of Boston Fern, the course of which has been worked out through studies carried on at the Brooklyn Botanic Garden, and is illustrated by the chart above.

"On the pedestals in the center are specimens of the wild 'Sword Fern,' the 'Boston Fern,' and its seven primary mutations or sports: 'Pierson Fern,' 'Harris Fern,' 'Scott Fern,' 'Foster Fern,' 'Roosevelt Fern,' 'Giatras Fern,' and the 'Gretna Fern.' On the bench at the right—with some overflow in the next house—may be seen practically all the other varieties shown on the chart together with some additional forms from England and elsewhere.

"In the chart, the varieties indicated by arrows show some reversion in characteristics toward the Boston Fern. All the rest represent progressive variations away from the Boston Fern. A considerable number of new varieties have appeared in the Garden collections."

A second frame in the same house is being installed containing photographs of some of the most common table ferns together with text descriptive of their cultural qualities. The aim of the Brooklyn Garden is to make this fern collection as educative for visitors as possible, both as to proper names of the various forms and as to

Nephrolepis Chart

A copy of this chart has recently been installed in house 10 of the Brooklyn Botanic Garden greenhouses. In this house there are two groups of cultivated ferns. Accompanying the chart, and arranged partly according to the

A Lesson on Beautifying Home Surroundings

ARTHUR SMITH

FROM what was said last month it will no doubt be gathered that landscape gardening is very sharply distinguished from gardening. The successful practice of the former depends on the practitioner having an artistic temperament; an intense love for Nature; an intimate knowledge of plants with their preferred environments, and upon being familiar with all the many necessary preparatory details connected with garden making as a whole. Landscape gardening is making pictures with plants; while gardening is the growing and care of plants without reference to the picture. The entire motive of the true landscape gardener is to make a pleasing picture, which picture must have a landscape or natural effect.

As compared with the formal or architectural style of laying out grounds, the naturalistic has among other advantages, that of giving an infinite variety of effects extending throughout the entire year. As F. Schuyler Mathews wrote, "Nature puts so much variety into her reality that she is more beautiful than we can imagine." There is no monotony in Nature.

Those who have studied and understand Nature's method of grouping plants and who carry out the principles are not likely to plan the monotonous system of arrangement too often found in gardens.

It has been well said that a landscape has three dimensions—length, breadth and height. A consideration of the latter is of the first importance in avoiding monotony and unnaturalness. Those who have admired wild, sylvan scenery, realize the delightful attractiveness of its composition. Although it may lack the more conspicuous and strikingly floriferous species which we use in gardens, the effect as a whole shows very clearly what may be accomplished by good grouping, irrespective of the plant material used.

What a marked contrast to this is seen in many gardens. Plantings consisting entirely of shrubs are made and composed of a few species which grow into more or less long, monotonous looking belts of about the same height, with a flat, inartistic surface. Sometimes, to make such cases ten times worse, the natural beauty of individual shrubs is frequently extinguished and the production of flowers is to a greater or lesser extent—according to species—prevented, by shearing; by this means a uniform height is maintained, and absolute ugliness created.

The fundamental principle whereby a beautiful and inspiring picture can be made is to have a broken sky line combined with a billowy and wavy mass; bearing in mind in this connection what the plants will develop into, rather than what they are when planted. Shrubbery should always have some evergreen species intermingled with it for the sake of Winter attractiveness; evergreens also make for more seclusion which is so desirable in a garden.

While the above should be considered in all groupings, the boundaries of our home scenery should be made, by means of suitable plantings, to assume the irregularity of natural outlines, and at the same time when possible, advantage should be taken of any outside landscape effects as to prevent any limitation of boundaries to appear from the residence; this can generally be accomplished by having one or more places where the planting is confined exclusively to dwarfier species.

Another bad arrangement is to make the boundary planting follow the fence line so strictly and to be of

such uniform width all along, that the general view is not much, if any, superior to that of a mere hedge. According to the area of ground to be dealt with, more or less pronounced bays and promontories must always be a feature of belt-plantings, if for no other reason than that they increase the apparent size of the garden.

In following with the eye the salient points of scenery we find it composed of lights and shades. These are produced by undulations, and the undulations again are produced by promontories and bays. While every effect has its outline, it should be so broken that none can tell where the boundary of each particular scene finishes. The various impressions observable from lawn to skyline should group themselves together as harmoniously as the leaves group themselves into masses, and as these masses again group themselves into the outlines of a fully developed tree.

The question of straight avenues of uniform sized trees comes to mind at this point. Unnaturalness of planting anything in straight lines must be obvious to most people who give any thought to the matter. At first sight a long avenue of trees may give pleasure through grandeur, historic association and age, but the same grand development along natural lines would add incomparably to the permanency of the pleasure to be derived. Walk through the grandest avenue and it will become tiring and monotonous to our sight long before the end is reached, and it will certainly fail to afford continual satisfaction. On the other hand a drive, however long, bounded by naturally arranged and broken groupings will ever satisfy; never become tiring to the senses; the ever-varying light and shade will lend new impressions; changes are created by every shift of sunlight and season, and it never fails to charm however frequently it may be seen.

The smaller the place the more objectionable do avenues and straight rows of trees become.

Throughout the year the unfolding and waning of plant growth gives forth continually varying and charming effects, not only in connection with one species planted alone, but more so when many species are planted together. To plan successfully the landscape development of land one must be thoroughly acquainted with all the changes to be observed at different periods of the year, otherwise there is danger of merely having certain effects for a short period in Summer and nothing which amounts to anything for the rest of the year. The aim of the designer should be to create a scene which will be more or less effective all the year around.

A great mistake is sometimes made when too many individuals of one species are planted together. It is true that in very extensive plantings upon large estates these individual groups may be larger than upon small ones, but even then the margin of difference is small. We should aim to intensify as much as possible the changes in effect which the seasons bring forth by having as great a variety as the area will permit, so that in any month throughout the year we can discover subjects for pleasure and admiration. When the senses have been gratified by one particular form and color, still others should be found to carry further and higher this sense of gratification; this may be obtained by passing from the observation of the characters of one species to that of others. Too much of one thing at one time—however good that thing may be—creates an unpleasant

feeling of satiation at one period and a void at another.

The effect of Time upon landscape development should have full consideration, although some people appear to forget this altogether, and they fail to understand that each year will see produced many new, delightful and surprising impressions. It is true that one may have moved on to their place trees of ten, twenty or more years old, and so produce at once effects which would require such number of years to develop if a start were made by planting young ones. Many people, however, find it intensely interesting to watch things grow, and by the use of young stock not only is this pleasure obtained, but there is a vast saving in the initial expense.

In studying how we may render our grounds beautiful, not only for a few months only, but for years, it will be necessary to have recourse to means adapted to the end. Some things endure but for a season, while others last for whole hundreds of years. Three points require our closest attention in respect to planting—permanency of effects, future effects, and present effects. In all our operations the various so-termed permanent plants must prove the basis. Ever-bounteous Nature has provided these in sufficiency for every display, the flowers taking precedence in Summer, rich colored foliage and fruit in the Autumn, and the continuance of fruit with evergreen foliage through the Winter.

It is not possible for any one to form a correct opinion upon a landscape planting unless they are thoroughly acquainted with the characters and habits of the material of which it is composed, and are also capable of visualizing the possibilities of its ultimate development. Many, in fact all, of the best in the way of trees do not show their fullest beauty until touched up by the hand of Time. In arranging all long-lived subjects the after effects must have full room to develop. Too often what may be termed future or prospective effects are not held in sufficient account. Sometimes in order to satisfy the owner's impatience for immediate effects landscape men, against their better judgment, plant too closely. Perhaps there would not be so much harm in this were thinning-out done at the proper time, but unfortunately this thinning is deferred until it is too late to prevent the harm being done. Were such matters seen to when required this might be obviated and quick-growing, short-lived subjects would not then be allowed to injure plants of a more permanent description, nor would good plants be allowed to destroy the beauty of each other by having to struggle amongst themselves for life. The duration of plants, to whatever class they happen to belong, holds an important place in our arrangements, for plants of the longest endurance are invariably the most worthy of the highest rank in our esteem.

Not only during time measured by years do we pass from one beautiful effect to another, but each succeeding month throughout the whole course of every year should have some special feature of beauty connected with it.

Some people are able to always live under conditions of more or less perpetual Summer; they may have a residence at Palm Beach, and another in Maine, with perhaps one in between these places, but they cannot, however, be said to have a home in its real sense and they know little or nothing of the continuously beautiful landscape effects which it is possible to create at one spot. With the majority the home landscape is always present and it should always be attractive. If it is not so, and if at any season there is lack of something interesting it shows lack of forethought in its planning and development. As John Burroughs said: "The Book of Nature is always open Winter and Summer, and it is always within reach and the print legible to those with eyes to read it."

We have emphasized the necessity for having the house harmonize with the country, and the more pronounced the discord between the house and its surroundings the less artistic will be the home. Naturalness is also always lost to a greater or lesser degree by drives and walks. These must be looked upon as necessary evils, and our object should be to minimize as much as possible their effect by reducing their area, and by constructing them of such material as will render the inevitable discord as little pronounced as possible.

Naturally the distance of the residence from the public highway and the extent of the ornamental surroundings, affect the length and number of the walks and drives. Sometimes the contour of the grounds enables the main entrance drive to run more or less below the natural gradé. When this is so it is advantageous, inasmuch as the drive is to that extent invisible excepting when one is actually upon it. It is of considerable importance that a drive, which practically amounts to a lifeless line of gravel, should not intersect the grounds in front of the house, as it then becomes a disagreeable object, and it should not interfere with the general artisticness of the landscape plan.

As a good approach does more than anything else to create a favorable first impression, the entrance, which is the first point seen, should be in accordance with the style and size of the place, and it should be so adequately dealt with as to not only prejudice one in favor of it, but it should also be so arranged as to give a fair index of the general character of what may be expected of the grounds themselves. If the entrance is recessed from the street, the area of such recess must depend somewhat upon the size of the place and the distance to be traversed before the residence is reached. Obviously it would be out of harmony to have a very imposing entrance, deeply recessed, in connection with a small place with the house only a hundred or so feet from it.

The amount of, if any, architectural work in the form of brick, stone, or iron, connected with the entrance depends entirely upon the conditions. When gates are considered necessary, obviously they must have some kind of pillars to support them, but when such are not required and the entrance is in purely natural surroundings, the less of architectural effects the better.

Again alluding to the above mentioned point that an entrance should be some index to the character of the interior, it is very important to avoid violating what may be termed a fundamental principle of good taste, by any undue ostentatiousness in its treatment, especially if this is combined with a picayune treatment of the grounds inside. Cases of this kind become on a par with the biblical whited sepulcher, or as one writer puts it, like the elaborate, gaudy entrance to a ten cent show.

Whatever the subsequent direction taken by it, it is invariably best for the first portion of the drive to be at a right angle to the public highway, although it may sometimes happen that some modification of this rule may be advisable.

As a drive is for the purpose of reaching the house it should proceed there as directly as possible, at the same time graceful curves may be introduced when such are permitted by the conditions. Its course and direction will be chiefly modified by the contours of the ground and it should avoid passing through deep depressions or over high elevations. In principle, no curve in a drive or walk should be permitted unless there is an obvious reason for it, and meaningless snake-like turning and twisting are in worst possible taste. All curves should be gentle, and they should only be used to avoid something. When a

Orchid Exhibit at the Missouri Botanical Garden

GEORGE H. PRING

OF recent date the garden orchid collection has been considerably augmented by the donation of the noteworthy Brownhurst collection, by the late D. S. Brown, of Kirkwood, Saint Louis. This splendid private collection combined with the garden botanical orchids, places it as one of the foremost of public collections, making it possible to present an exhibition equal to any other botanical garden exhibition.

In previous years, the flowering plants have been shown in mass formation arranged in alcoves upon tiers of stages which seem to be the adopted method. Occasionally we find the stages camouflaged with cork bark and then again we find rockeries built in artistic design. These pseudo creations have been used at the garden at various times despite the fact that it is misleading to the general public in so far as imparting habit of the growth of the plant and especially where the epiphytes are grown in pots, is it impossible for the layman to understand the difference between epiphytes and terrestrials or the saprophytes when they are all shown as one class. Previous years when people have been viewing the flowering orchids, one will frequently hear remarks as: "Oh, here are the orchids! Why, I thought they grew upon trees!" "Sure," replies the companion. "They're parasites." It is therefore manifested that the public should be enlightened as to the characteristics of the orchid by arranging the plants in a replica of their natural environment. The most familiar flower to the layman is that of the large mauve colored *Cattleya* and without this flower in quantity, there are no orchids, despite the fact that hundreds of other species and hybrids are shown.

In view of these manifestations, the garden has deviated from the average arrangement so that the visitor may study the individuality of both flower and plant, thereby familiarizing himself with the different habits of the

orchid and likewise suggesting that there are just as many showy orchids outside the genus *Cattleya*. The most natural way to educate the public is by copying the orchid as grown in the tropics. It was therefore decided to use the floral display house (Banquet hall for the N. A. G. Convention, 1920) so as to reproduce a replica of the Cordilleras of Colombia and Venezuela. During the past year all dead trees were collected from the garden arboretum and city parks, the

tops being used after they were cut to a height of twenty to twenty-five feet and the side branches cut to a convenient shape. Twenty-five of these trees were brought into the house and arranged in forest formation, interspacing with tall growing palms and overcoming the bareness of the branches by the use of *Tillandsia usneoides* in festoons. These trees were embellished with all the flowering epiphytes as *Cattleya*, *Lalia*, *Lachocattleya*, *Brassocattleya*, *Vanda*, *Acridos*, *Epidendrum*, *Coryanthes*, *Denrobium*, etc., and arranged so as each specimen could be readily distinguished from the other. The spacious brick floor was entirely covered with six inches of partially decomposed leaves, as one would expect to find when travelling through the forest, even the walks received this covering so as to suggest the beaten trail, so much so, that visitors at first were afraid to traverse the suggested area, thinking that the entire space was reserved for the display. All the terrestrial orchids were arranged beneath the

A glimpse of the orchid exhibit at the Missouri Botanical Garden

trees countersunk in this leaf mulch so as to hide the pots and to give the impression as if they were growing naturally in the ground. Ferns were used in combination with such terrestrials as *Phragmopodium* (*Selenipedium*), *Paphiopedilum* (*Cypripedium*), *Tainia*, *Habenaria*, etc.

The press has been highly complimentary upon this exhibition, giving it wide publicity. The January attendance has been greater than any previous year, five thousand visiting the show during the opening afternoon.

God's Best Berry

STRAWBERRY propagation in a private garden, whether the area be big or little, should be regarded as a business of importance. It is in the nature of a casual matter with the field grower. If the runners root, well and good; if they fail, well, better luck next time. We will leave the latter to his gambling wheel of fortune and consider the subject from the point of view of the gardener who, as far as is humanly possible, turns the wheel himself.

Three fundamental points are: 1, the plant from which the necessary runners shall be taken; 2, the type of runner which shall be chosen; and 3, the manner in which it shall be rooted. As a general rule the private cultivator has entire control over each of these though, in some circumstances, he may be forced to proceed as convenience, not as judgment, directs. The points may most usefully be dealt with as set out.

It is accepted that one year old plants will, in normal conditions, produce the finest runners or plantlets, especially, perhaps, those which have proved their power of fruiting by giving blossoms, but which have not been permitted to pass beyond that stage. There have been unnumbered controversies to decide whether runners from a barren plant (*i. e.*, one which has never developed a flower truss), will be similarly barren, but the issue has never been authoritatively reached. If there were no risk the question could never have come up for discussion. There is a risk and it is not worth taking. Therefore, the decision must be in favor of the fruitful parent, with the supplemental one of choosing one year old plants, if possible. Should these be, for any uncontrolled reason, unavailable, the second choice must be from two year old plants, and the third, and final, choice from three year old plants.

Apropos the runners themselves. The strigs are prolific in the production of plantlets, and propagation may be, consequently, carried to an intense degree, but this is more than doubtfully wise. Healthy plants in a clean plantation will send forth so many strigs that the requisite number of youngsters will be provided by the first or second plantlet, or, in the event of necessity, both. Should a desire be felt to split hairs, and decide whether the first or second plantlet is the better, the best advice that one can give is for each grower to please himself, since, judging from the broad basis, there is no perceptible difference in the final results.

Now as to manner of layering, which is one of the simplest forms of propagation. The strigs carrying the runners extend in all directions from the parent plants and many of these will attach themselves securely to the soil so that the species may be perpetuated. This is a natural method of increase and the gardener adopts it as the best, but wisely carries it out under a definite system. He selects the best suitable plants and the most promising plantlets and runs the process as in a set of harness. Three modes of procedure are popular, easy, certain, and all are based on the best plants, best runners principle.

The most common way, probably because it is the least trouble, and, incidentally, the worst, is to cleanse the alleys of weeds, attach the plantlets to the soil with small stones or pegs and await results. Undoubtedly better is to supplement the cleaning by surfacing with good mould, as this conduces to superior and quicker rooting. The chief disadvantage occurs when transplantation must be done in hot, dry weather. The soil falls from the roots in lifting and the plants may, consequently, sustain a check to progress. This may not be a substantial dis-

ability in general culture, but those who aspire to achieve the finest results regard it with suspicion and strive to avoid it.

The second and third methods are very closely akin and may be treated of in association. The one is to plunge 3-inch pots filled firmly with light compost in the soil, and the other is to substitute 3-inch squares of turf, grass side downwards, for the pots; plantlets to the necessary number are attached to the soil in the pots or to the inverted turves, as the case may be, and water is given as imperative to prevent total dryness. Each is excellent. The roots come rapidly and numerous, they are retained within a circumscribed area and moving to pots or open quarters can be done with the ball of soil and roots intact. There can, then, be no cessation of advance. Turves are preferable to pots for one important reason. If the move to fruiting pots or rows cannot be carried out at the correct moment—that is to say, when the young roots are working freely round the ball—matting commences against the cool, porous, impenetrable walls, the roots become hard and wiry in texture and growth is arrested after transference. The slight, undesirable check has been inflicted. With turves this cannot occur. The roots may go beyond the limits specially provided, but, passing into soil, do not change their character and the plants do not cease to advance, even momentarily, after removal.

A final word or two of insistence on the necessity of instant work and the subject must be left. Early rooted runners are invariably the best and giving, as they do, the grower power to proceed as he wishes with them, bring supreme satisfaction. Some gardeners have made big strides in the task, others have just started and many are waiting—for they know not what. To one and all it may be said: Proceed instantly, work rapidly and thoroughly to produce rooted plants ready for their fruiting quarters at the earliest possible moment.

THINGS AND THOUGHTS OF THE GARDEN

(Continued from page 40)

Salisbury Plain. The moors are made up of a wet peat soil of a distinctly acid type, relatively poor in mineral salts. This of course is practically useless from an agricultural standpoint although it may have some value for pasturage and grazing purposes. On soil of this type we find *Calluna* and other Ericaceous plants in abundance associated with *Ulex Europæus*.

Many of the downs are also valueless from an agricultural standpoint, although some of them provide admirable pasturage for sheep. This because of the fact that the soil overlying the chalk is thin—in many cases it is only an inch or two deep—and in consequence is unable to support any strong growth of vegetation. The prevailing type of vegetation is distinctly calcicole in character, the flora differs from that of the moors and includes such plants as *Helianthemum Chamæcistus*, *Asperula cynanchica*, and various terrestrial orchids.

GARDENERS' CHRONICLE, 286 Fifth Ave., New York.

Work for the Month in the Garden

SAMUEL GOLDING

BY this date all plans have been made. Stocks of necessary seeds, tools, fertilizers, spraying materials, and other sundries will soon be ordered; mowing machines overhauled so that there will be no delay to take advantage of prevailing conditions, when we can, with confidence, resume sowing. Although February may be regarded by many as too early, owing to lack of artificial heating arrangements, yet the longer days and brighter sunshine remind us that the gardening season has opened in earnest. Where abundant facilities are provided for growing early vegetables and flowers, no time should be lost. It is the aim and object of all growers to prolong the season when fresh vegetables can be obtained, and if one can produce them for the table even a few weeks earlier than they can be had from the open garden, they are always appreciated and are more than worth the extra labor involved.

The greenhouse, pits, and frames are the mediums through which we can achieve this desirable end, whether plants are grown in them to maturity, or whether they are merely used to give the plants a start, to be afterwards planted outside to finish their growth, thereby gaining much valuable time. Where space is limited, some caution is necessary in starting seedlings, unless it is that one particular crop is specialized in. Where many subjects are grown, the question of proper room for development becomes a vital problem. To insure success, one must always endeavor to keep the plants moving from the seedling stage to maturity, but the grower is governed by the local conditions which confront him.

If abundant fermenting materials for the hotbeds have been collected, and the pits filled as advised in the last issue of the CHRONICLE, they should be in perfect state for seeding and planting before February is passed. It is necessary when making up a bed to have in mind its particular function—if it is to raise a crop of beets, carrots, or cauliflower, which finish their growth where planted. These will require a steady and lasting heat which can be obtained by mixing a larger percentage of oak or beech leaves with the stable manure, and then covering this with a good compost, a depth of five to six inches. If the hotbed is made up solely for raising plants, then the bed should be covered with enough soil to absorb the rank ammonia fumes, and prevent damage to the tender seedlings from a too violent heat, which induces a rapid germination and possible damping off, if not very closely watched.

Sow batches of horn carrots, beets, lettuce, spinach, cauliflowers, cabbages, radishes, and small salads. Sow in pans or flats onions, leeks, tomatoes, egg plants, peppers, and celery for early work.

Continue to bring in successional batches of vegetables for forcing, which quickly respond to the influence of a little heat at this time. Their growth is very rapid if a humid, growing atmosphere is maintained.

Make up additional mushroom beds as the old ones show signs of exhaustion. Push on with any outside work whenever the climatic conditions permit. Finish up with all speed the pruning of fruit trees, and the Winter spraying of trees and shrubs. The San José scale is very partial to the lilac and it is advisable to keep a sharp look-

out for it. *Euonymus radican* growing on walls is often subject to attacks of this pest and should be sprayed as a preventive measure.

Give abundance of air, whenever it is possible, to plants wintering in the cold frames. Remove the sash on mild days; pick off all decayed foliage; keep the top soil loose about the planted stock by going over with a small cultivator. Have on hand a good supply of covering material in case of a spell of severe weather.

This is a splendid time to sow sweet pea seed, for the best results can be expected from seed sown now. Sow in pots or flats, and place in a frame; after the seed germinates, grow on as cool as possible, to develop strong, vigorous root action and sturdy plants for setting out when the ground is fit for their reception. Use fairly light soil in the flats so they can be easily shaken out with a minimum injury to the roots when planting season is here.

MARCH

The advent of March means busy days for the gardener. All available space under glass will be doing its maximum amount of service. A full line of vegetables and flowers may be started at once with every confidence of the ultimate results. In addition to the above mentioned varieties, dwarf peas and potatoes may be planted, and successions of the very early ones sown when necessary, so as to maintain a perfect supply. It is a most unsatisfactory state of affairs to have a glut at one period, to be followed by famine.

The raising of plants for Summer bedding will demand immediate attention. Propagate cuttings of geraniums, fuchias, *lantana*, heliotrope, *coleus*, *ageratum*, and other stock on hand. Sow as early as you can, seeds of *Begonia gracilis* and *semperflorens*. As the seeds are very minute, they require a longer period to develop into good sized plants for bedding than the average annuals.

Sow *Salvia splendens*, *S. patens*, *S. azurea*, *S. farinacea* (while the last two are not really annuals, they thrive well if treated as such), *Browallia speciosa*, *Celosia plumosa*, in its varied forms. These are a few of the most important popular plants which take a longer period of growth before they can be used for ornamental purposes than do many other annuals. The average annual is a fairly rapid growing subject and one must be guided as to sowing by the probable date when their bloom will be desired. If successions are required, they should be started at the earliest opportunity. Many annuals do better when sown outside on the place where they are to bloom.

Seeds of Fall blooming perennials can be sown now, and they will make fine plants for setting out in the border during May. Seeds of Delphinium in variety should be sown soon to have bloom during the coming Summer. The seedlings of the hybrid types should be planted together in blocks as they have a wide range, and varied shades of coloring. When grown together, it is less difficult to select the more desirable ones as to color and type. They can be lifted the following season and planted in the flower garden; the one year old plants are most vigorous. Their wonderful spikes are one of the glories of the garden during the early Summer days.

The Greenhouse, Month to Month

W. R. FOWKES

MARCH is a busy month. The powerful rays of the sun make more demands on ventilation. Seedlings need to be watched and carefully shaded.

The pot fruit trees have arrived at an important period; peaches and nectarines being the leading fruits raised in pots. It is not prudent to try to grow cherries, plums and pears in the same compartment with the nectarines and peaches as they require much syringing to check red spider. The cherries, etc., ripen their fruit much earlier, and if they are syringed when showing color, they will crack and be ruined. With regard to the plums, if they are syringed when the fruit is ripening, much of the fruit will crack and the dense bloom will be destroyed. Hence the reason for separate compartments. The south, or warm end, should be used for the peaches and nectarines; the cooler partition for the cooler fruits which have been named.

As the fruit trees come into flower, give as much air as possible, avoiding cutting winds. Air is essential for the setting of their fruits. As there are no bees at hand, take a rabbit's tail, tied to the end of a cane, and at noon when the pollen is open and dry, gently tap each truss. Watch carefully the setting of the fruits, but do not try to hurry their progress with heat, as this would prove fatal. Fifty degrees at night must never be exceeded until after stoning is passed. When the fruit is set, syringing must be practised; do not use force to injure, and keep a humid atmosphere.

If grapes are grown in pots, they must be grown on the alternate system; by allowing the plants to do one year's work and then to have one year's rest.

The fig is one of the best of fruit trees for pot culture, although the culture of figs is not always attended with the success one might wish for. This often is due to the wrong methods employed. The fig, in the first place, has a tendency to strong growth. It is also a gross feeder and if unchecked and grown in too rank a soil, will be a barren tree. Grown in an intermediate temperature in the same soil which is used for peaches, it should thrive well.

Pruning must be performed with discretion. If a very strong shoot appears, it is better to cut it clean out than to prune it to two or three eyes. Pinching hardens the wood, thus making the tree more prolific. Therefore grow in fairly strong soil; get a medium texture of wood; pinch from the fourth leaf, and you will rarely be disappointed by having a useless fig tree.

Naturally a proper selection of suitable varieties adapted for forcing must be adhered to. It must not be imagined that all varieties are especially good for forcing, although most of the best and largest sorts in cultivation are suitable for that purpose. Any first class nurseryman whose advertisement appears in the CHRONICLE can supply them. Selections can be made from the following: *Theresa de Mel*, *Early Violet Negro Largo*, *Brown Turkey*, *Black Marseilles*, *Brown Ischia*, *Violet Sepor*. Overcrowding and growing in too shady a position must be avoided, as well as too much fertilizer, as both help to encourage an unfruitful growth in fig trees.

Caladiums that have nicely started and are wanted for Summer work should be transferred from flats to pots. Use a little chopped sphagnum moss and sand in the loam,

and an inch of crocks. Keep pots close together in a warm, humid, partly shaded place for three weeks until the growth has started off well.

Tuberous begonias and the next batch of gloxinias should be placed in flats of moss and sand soil, and kept on the dry side. They will provide a succession of blooming plants that are needed when we are through with many of the Winter bulbous stock. Propagate Lorraine Begonia by leaves. Insert healthy leaf stems half their length in the sand, not allowing the foliage to come near the sand. Six weeks' time will complete the operation.

As we are crowded for space at this time of the year, some subjects can be grown suspended from the roof, without injuring any plants beneath them. We can procure pot hangers from reliable firms, which are light, yet strong enough to hold any kind of plant. E. T. McCarroll has suspended Farleyense ferns over orchids; also begonias and many other plants in five- to eight-inch pots. There are plants which we cannot always grow in wire baskets, and the pot hangers are certainly excellent for that purpose. Mr. McCarroll kindly informed me that he secured his from Joseph Manda Company and that they are a decided improvement on anything he had used before.

Roses are in need of more syringing, but as their wants are so generally understood, it is hardly necessary to devote more than a passing remark to them.

Wallflowers, *Kewensis*, come into their own now and are sweetly scented flowers that give promise of Spring.

Immerse the baskets containing *Oxalis* into a pail of soot water every week.

Bougainvillea and *Clerodendrons*, *Thompsonii*, are starting up nicely for Easter. These heat loving subjects must be gently syringed. They can be trained to any kind of support.

Aristoclochia Sturtevantii is an interesting plant to adorn the conservatory in Summer, and is easily raised from seed. It requires rather poor soil.

Sow a packet of *Grevillea robusta* and *Aralia Sieboldi*. They both make useful plants for Summer decoration and as they are biennials, they can be used indefinitely.

Sow also a packet of *Francoa ramosa*, known as the Bridal wreath. It has an advantage over many other useful plants in that dust and a certain amount of neglect seem to suit its nature.

Calanthes that have bloomed and have rested are starting out on their journey and the better method is to mix a light compost of peat, sphagnum moss, sand, a little mushroom manure, and loam that is fibrous. Place in three-inch pots and do not water until growth is active. A shelf near the glass in a warm spot, or underneath the tomato vines is another ideal place for them.

Now that the tomatoes are in full crop, instead of taking off-sets away cleanly, encourage a few of them to grow. When the crop is perfected, cut out the old, main stem and the new growths will be filled with bloom, and a fine crop attained. To succeed the others, grow the new "Golden Sunrise." It is a novelty, which has proved its worth.

If cannas are desired for flower beds this Summer, they should be started the end of March. Mix a light com-

A Garden of Blue Annuals Edged With White

FLORUM AMATOR

BLUE, the color of the sky, and the symbolic hue of hope, is especially delightful in a Summer garden, giving, as it does, a suggestion of grateful coolness in contrast to the Summer's heat. A garden of blue flowers, edged with white, produces a charming effect.

We have no very tall-growing, annual blue-flowered plants; therefore we will not be perplexed with arranging our beds of plants so that the taller will not shade the lower. However, our garden will be more attractive if we arrange to have the taller plants in the northern beds or borders of our garden.

Let us, therefore, in one of the northern beds, plant the rich dark-blue, and in another the exquisite azure-blue annual Lupines. Their pea-shaped flowers are lovely, and delightfully fragrant, and their foliage is beautiful. They may be planted in the open garden in May and thinned out when small to stand out ten inches apart each way. Lupines grow quickly and their cut blooms are excellent for table use. We may plant as an edging for these beds *Ageratum* ("Little Dorrit"), the white variety, sowing the seeds where the plants are to grow and thinning them when young to stand about three inches apart.

Within the last few years we are beginning to grow a little more freely in our American gardens that beautiful annual *Salpiglossis* ("Painted Tongue"). We should indeed have a bed of these of the orchid-flowered type of purple-violet color, and another of the light blue with veins of gold. The funnel-shaped flowers of *Salpiglossis* face upward and are exquisitely marked with veins of gold or silver. They produce a wealth of flowers, which are highly esteemed for cutting, from early Summer till frost. It is better, if convenient, to sow the seeds in fine soil in shallow wooden boxes, and place these in a sunny window of our dwelling house or in a conservatory or hot bed, and after frost is past to transplant the young plants, when of suitable size, into the garden bed about eight inches apart each way, but the seeds may be sown in May in a bed of finely prepared soil in the garden in very shallow drills eight inches apart, and the plants, when they are small may be thinned out so that those left will stand about eight inches apart in the rows. There is another and a better way of sowing all flower seeds directly in the garden where they are to grow, namely, make drills of such depth as the seeds require at a suitable distance apart; then make others crossing the first at right angles and at such a distance apart as you would like the plants to stand in the row. Plant two or three seeds at each point of intersection of the drills and when the plants are a few inches high, pull up at each intersection all the plants except the strongest. Suppose we edge our beds of *Salpiglossis* with the pretty, little white *Lobelia compacta*. We may sow the seeds indoors and transplant, or directly in the bed and thin out the plants to stand about three inches apart.

I think we would like beds of the two types of double blue annual Larkspurs, one of the Stock-flowered type of sky-blue color, and another of dark blue of this type, one of the Emperor type in either black-blue or violet and another in either light blue or azure blue. The Stock-flowered type bears its blooms in columnar or pyramidal spikes; the Emperor type has its inflorescence in candelabra form. Larkspur seeds should be sown directly in the garden beds in May, and, when large enough, thinned to stand about six to eight inches apart. The plants will begin to bloom in July, and continue to furnish an abundance of beautiful flowers, which are excellent for cut-

ting till frosts appear. *Alyssum* ("Little Gem") sown directly in the garden bed and thinned out to stand about three inches apart will make a very pretty edging for our Larkspur beds.

There is a beautiful lavender-blue variety of *Scabiosa* (Sweet Scabious) whose flowers are borne on long stems, and are very suitable for cutting, and are produced continuously from July until frosts come. *Scabiosa* seeds may be sown indoors in early Spring and the plants transplanted into the garden later, or in May sow directly in the garden beds. We will, I think, edge our *Scabiosa* bed with *Alyssum procumbens compactum*, commonly called "Carpet of Snow," sowing the seeds directly in the garden bed and thinning out the plants to stand a few inches apart, when they are small.

There is a new and greatly improved variety of that unique plant, *Nigella* ("Love-in-a-Mist"), named "Miss Jekyll." It grows about three feet high, and has lovely flowers of cornflower-blue nestling amid its pretty, feathery, green foliage, the position of the flowers as regards the foliage giving the plant its common name. *Nigella* is among the hardiest of annuals, and may be sown directly in the garden in the south in Autumn, and in the north in early Spring, or later in May. It should be thinned like other plants to stand a suitable distance apart. We never obtain the best blooms either as regards size or quality when the plants crowd each other. *Nigella* is especially useful in combination with other flowers in making up bouquets. We would like, I think, an edging of white *Lobelia compacta* for our *Nigella* bed.

Shall we not have a bed of that old time, floriferous, fuzzy flower, blue *Ageratum*, planning the variety, "Swanley Blue," because it grows tall enough for cutting, and edge our *Ageratum* bed with fragrant white Sweet *Alyssum*, that dear, old-fashioned variety which blooms till November snows begin to fall?

Browallia, commonly called "Amethyst" from the color of the flowers of some of its varieties, is too little grown. I think you would like a bed of this of the variety *speciosa major*. The beautiful ultramarine blue of its blooms, one of the rare colors in flowers, will certainly delight you. You will need a very dwarf plant for bordering your *Browallia* bed, and you can again plant *Alyssum* ("White Carpet").

Let us save the last bed in our flower garden for *Myosotis* ("Forget-me-not"), using the variety *semper-florens* because it is a continuous bloomer, and also some of the much admired, large-flowered, new variety, "Ruth Fischer." Our Forget-me-not bed should have for a border a plant bearing a very small flower of somewhat the same form as that of the Forget-me-not, and I think we would like for this purpose *Alyssum* ("Little Gem").

There are a few other flowers which we might grow in our blue garden, such as *Centaureas* ("Cornflowers"), purple sandytuft, purple *Verbenas* and blue *Violas*, but, perhaps, what we have arranged for will be sufficient for the first lesson.

Of course you will follow the advice of Pliny, the Roman, in making your blue garden, namely, "Dig deep, manure well, work often." We have mentioned May as the time for planting the seeds of annuals, but they may also be planted in June, if the soil is kept moist while the seeds are germinating, and the plants from June seed sowing will bloom in middle or late Summer or in Autumn.

Plants of the Bible and Biblical Lands

FLOWERS pressed and sent home from time to time during the recent war as well as the sojourning of so many of our soldiers in "the far east" have brought Biblical lands very close to us, and it may be interesting to some to have their memories refreshed in regard to the living things that spring from the sacred soil of such lands as we find mentioned in Holy Writ. Anything connected with Palestine especially, whose hills and valleys Our Saviour trod and whose rocks re-echoed the very words He spoke, must have a vital interest for each one of us, and there is wonderment in the thought that our eyes can behold today the very same kinds of flowers and plants that perhaps He looked upon and drew lessons from in His teaching. For in the Holy Land, conditions have apparently changed very little if at all since Our Lord's time, and we find the same manners and customs prevailing today as those which were in vogue over three thousand years ago. In other countries as time sweeps on, fashions come and go and progress is made in different directions, but Palestine, Syria and the greater part of Egypt as well as the Sinaitic peninsula remain unchanged, one of the features which strikes the traveler most being the marvelous antiquity and uniformity of the customs. Not only do these remain the same but also the bulk of the language, together with the productions and great natural features of the country. The shepherd may lead his sheep in A.D. 1919 over the very hillsides frequented by the "Shepherd King." The traveler on his way may still pluck the ears of corn and allow his horse to feed in passing on the unenclosed crops of barley, or "eat his fill of grapes at his own pleasure," as he goes through the numerous vineyards, with the single stipulation that he puts none into a vessel to carry away. In regard to the wheat and barley this practice is easy and natural as these crops are easily cultivated in Syria and Egypt, extending for miles over the country in one unbroken line and in good seasons yielding an astounding return. As the seed is still sown broadcast, every bit of the ground being cultivated, the ideas of trespass and prohibition do not exist, in addition to which there is the instinctive hospitality of the Eastern. The vineyards are enclosed and carefully protected from the depredations of robbers and wild animals, yet this charter of "the stranger and the poor" as given in the law of Moses (Deuteronomy XXIII, 24 and 25) is still respected and observed. The greetings and farewells are identical with those in the time of Abraham, although a little of the significance and spirit may have passed out of them. Going through the country parts particularly, one notices the adherence to the ways and things of the past. From the south of Egypt to the extreme north of Syria, the plough used today is the same as that employed in the earliest times and of the same pattern everywhere. It just serves to scratch the soil to a depth of two or three inches. If harvests were not so plentiful and crops did not respond so readily as they do in those favored regions, a little progress might have been made in the construction of this and other farm implements. Everywhere the excellent coffee is served out of the same little handleless cup, unvarying in size and design, and at entertainments the host still rises and after girding himself with a towel, washes the feet of his guests. Immutability has been well said to be the law of the East.

To the Jews and Greeks we are indebted for the earliest allusions in writing to plants and flowers, the former in the books of the Old Testament, the latter through the

works of their poet, Homer. The Old Testament gives us the first account of a piece of ground being marked out and set aside for the culture of flowers, in its story of the Garden of Eden, supposed by some authorities to have been situated in Palestine. Later on we read of the "promised garden of Mahomet" and the far-famed hanging gardens of Babylon in which King Solomon, an enthusiastic gardener and botanist, took such keen delight.

Doubtless the eyes of the Jews of long ago were not closed to the beauty and significance of the lowly things of the earth—David's utterances in the Psalms show that he must have lived very close to them—and they probably had acquired much knowledge of plant life during the period of their wanderings before entering the promised land. They were thus well able to read the book of Nature, hence the constant use made of it in Holy Scripture to illustrate some precept or inculcate some moral truth.

Flowers occupied a prominent place on every Jewish festival, when they wished to show honor to distinguished persons. In the Apocrypha—Wisdom XI, 6—we have a reference to this lavish use of wreaths which runs as follows—"Come on therefore; let us enjoy the good things that are present; and let us speedily use the creatures like us in youth. Let us fill ourselves with costly wine and ointments; and let no flower of Spring pass by us: Let us crown ourselves with rosebuds before they are withered."

To understand the nature of the vegetation and the Biblical allusions it is necessary to bear in mind the physical features. Taking Palestine first, from north to south, we have a narrow tract of country nearly all parts of which, in spite of the existing mountains, reap benefit from the west wind which blows from the Mediterranean during the greater part of the year. The Arabs very appropriately call this wind "the father of rain," but during Summer and Autumn it only gets as far as making night mists which are soon dissipated by the morning sun. There is great diversity of surface in a small space and consequently a great variety of plant life. Going from west to east we have along the sea-coast a plain extending for about 10 miles inland. This is very fertile with the exception of its coastal edge which is marked by the presence of sand dunes. These seem to be encroaching inland and in places are quite wide.

Amongst the plants growing on the sand dunes are *Artemisia monosperma*, a species of wormwood, with a very strong scent and a bitter taste; *Atriplex portulacoides* (Sea Purslane); Sea Rocket, a cruciferous plant with fleshy leaves; numerous prickly members of the ubiquitous Daisy family, including *Cyanea Syriaca*, with its violet colored flowers; *Cynomorium coccinium* of which the name alone is enough to startle anybody, a curious leafless, red plant covered with scales and parasitic on the roots of others, especially those belonging to the family of *Chenopodiaceae*; Cotton weed, a herb clothed with dense grey wool; Squirting Cucumber, of which some may like the botanical name—*Ecbalium elaterium*—with its thick prostrate stems, like long arms reaching out over the sand, rough leaves and small greenish gourds, startling the passer-by now and then by its explosive ejection of seeds; *Crambe maritima* (Seakale); *Jasmine officinale*, with its white sweet-scented flowers; *Reseda orientalis*; *Salicornia fruticosa* and *S. herbacea*, the latter leafless with spikes of flowers jointed like the stem; different species of tufted Grasses, which help to bind the sand together; *Thymelæa hirsuta*, a shrub

with minute fleshy leaves and small yellow flowers borne in clusters near the tips of the twigs; besides *Urginea maritima*, the bulbs of which are the "squills" used in medicine, and many others of more or less interest. It will be noticed that all are characterized by some provision having been made for the conservation of water either by a coating of hairs, thick fleshy leaves, or absence of leaves, or in some other way known to the plant dweller on the dune. Every bit of the plain is arable and as rain brought from the west falls from August right through Winter and Spring until the end of March, it is very suitable for wheat and similar crops. Every inch is under cultivation and in places like Jaffa, the modern Joppa, there are huge orange groves, with a few almond and fig orchards. Traveling through the plain in spring it presents a wonderful sight, with its large stretches of green wheat patched quite red here and there with anemones and later on with poppies of the most brilliant hue. On the inner edge the hills start and very soon get up to 1,000 feet above sea level, the height gradually increasing further inland to about 2,000 feet. They are cut by immense wadis or valleys running inland, which throw off branches, that in turn also branch. In any other country we might expect to find rivers speeding their way down these water courses but in the Spring of the year they are absolutely dry. However, the country as a whole does not suffer from lack of water owing to the existence of numerous springs and conservation by means of wells and rock cisterns or aqueducts.

Water is the most precious thing in the country, and of vital importance in those districts where springs and streams are rare. The bygone inhabitants set us an example by the way in which they recognized this fact, and took advantage of the periodic wet seasons to preserve as much of the precious liquid as possible, for use in times of drought. No labor, time, or expense, was spared in the pursuit of this object, and water saving was part of the scheme by which the desert—ever ready to devour—was kept from encroaching on their narrow strip of land. Josephus tells of an aqueduct 25 miles long which was made by Pontius Pilate, the governor of Judea, in order to bring water to Jerusalem, which had no natural supply in the shape of springs or streams. The engineers of that time must have had some difficulties; for the conveying pipes, which consisted of large blocks of stone bored through the centre, traveled in a direct line up and down the slopes of the mountains, and the amount of pressure required must have been considerable. Aqueducts are and always must have been common and familiar objects in the Holy Land. The pipes were generally made of earthenware laid in thick beds of cement, the latter largely formed of crushed pottery, which in course of time became as hard as stone. Sometimes passages for the water to flow were cut in grooves in the limestone of the hillsides; and in many places where no springs could be found, very rich sheiks have chiseled through rocks or drilled to depths of over 200 feet, in their efforts to find an artesian basin.

The irrigation systems along the valleys, through which the railway of today passes, are very ancient and date back to the beginning of things. The same streams are now used and the same methods applied for the directing and controlling of the water as prevailed in the time of Abraham. These old builders did their work so well that the pools, cisterns, and wells which they established still stand as monuments to their memory, and will be appreciated as long as that thirsty land exists. The beautiful temple of Solomon, with all its glory of pomegranate wreaths and cedar overlaid with gold, has vanished; but the three pools which he caused to be con-

structed with such care in the vicinity of Jerusalem, and filled with water, still remain, and are in constant use, forming the sole supply of the people of Bethlehem.—*South African Gardening and Country Life*.

A LESSON ON BEAUTIFYING HOME SURROUNDINGS

(Continued from page 48)

departure from a straight line is advisable, then there must be some appropriate planting placed in such a position, either before or after the drive or walk is made, so that it will be obvious that the curve was necessary to avoid the planting, or it may be some other object.

In constructing a drive through an extensive estate advantage should be taken of opportunities to obtain views of any points of interest in the surrounding country, and at the same time one should avoid, or hide, by suitable planting, any undesirable objects.

With small places the position of the house and drive require careful limited area. More can be made of a small lot by placing the house to one side of it than by placing it in the middle. In these days practically everyone has an automobile and a drive is necessary to reach the garage. This drive should be at the side, leaving five or six feet from the boundary for some planting, its subsequent direction depending upon the position of the service side of the house, etc. It is not advisable for the drive on a small place to proceed along the front of the house, as passengers can be deposited and taken on at the end of the verandah, along which they can reach the front door. This method entirely does away with any excuse for the existence of a walk running through the lawn, which is one of the most hideous features of the modern suburban home, especially when constructed of cement.

Such a drive should be entirely screened from the front lawn by suitable planting, and, with the elimination of the center walk, combined with planting on the other sides, a front lawn is then in the desirable condition of being unbroken and shut off from everything but the house.

According to the size of the place, subsidiary walks and drives have to be provided where such are necessary. Neither is artistic in itself. Every foot of walk or of drive is a trouble, an expense, and usually a distinct deduction from the beauty of a place. They should therefore be reduced to the smallest quantity that will fit the actual demands of the traffic about a place.

The least desirable form of garden walk is that constructed of cement. When a walk, other than grass is required in a garden, the least objectionable form to have is that composed of irregular shaped pieces of flat stone so laid as to be flush with the lawn—if it passes through one—the grass growing in the spaces between the stones can be cut with the lawn mower. These spaces may also have dwarf hardy plants growing in them when the walk is not through a lawn such as *Sedum acre* and *Thymus serpyllum*; when the latter is walked over a delightful perfume arises. Hard red brick, set on edge is from all points a better material than cement.

God Almighty first planted a garden. And, indeed, it is the greatest refreshment to the spirits of man; without which buildings and palaces are but gross handiwork; and a man shall ever see that when ages grow to civility and elegance, men come to build stately gardens sooner than to garden finely: as if gardening were the greater perfection.—*Bacon*.

Departments of Foreign Exchange and Book Reviews

THE AIR OF THE GARDEN

ONE of the most interesting features of gardening is the fact that it appeals to every faculty—most obviously to the sight, since form and color are generally the chief considerations in the selection and arrangement of plants, but none the less effectively to the others. It appeals to the ear in many ways, from the hum of the bees in the orchard to the call of the robin on a Winter's day. Even when the air is too calm to awake the rustle, the silence which falls is a positive influence rather than a mere absence of sound—the living silence of sleep, not the empty silence of lifeless surroundings. Its appeal to the taste is demonstrated forthrightly by the powers on whose lips the fate of new varieties of fruit depends. Its harsher effects may be experienced by anyone who will attempt to prune a *Berberis* with unprotected hands. Its most powerful influence, however, is exerted through the medium of the sense which, in the ordinary way, is regarded as of least importance—the sense of smell.

In everyday life the loss of this faculty would not be of serious consequence, but in gardening this is not so. A person who had the misfortune to lose both sight and hearing, but whose sense of smell remained keen, would not be entirely cut off from the pleasures of a garden provided he had previously acquired a store of memories which could be aroused by the ever-varying odors borne on the air during the course of a year.

The range of these is wonderful, and any strict classification of their varieties is at present impossible. Some are light, others are heavy; some are soothing, others refreshing; some, though not sweet, are vaguely pleasant, and others are frankly displeasing. The conditions controlling their production and effects—on insects as well as man—afford, like the question of autumn colors, a fascinating field for study, but, of the two, the subject of scents is the wider, since not only leaves but also flowers, fruit and even roots may be concerned in their production.

The strong influence of scent sometimes causes a conflict of ideas when the merits of a plant are being considered. Lack of scent may not tell heavily against a flower which, like many Roses, has beauty of form to atone for it, but it takes a great deal of outward attraction to outweigh an unpleasant odor. One cannot, however, establish a principle that no offender in this way should be permitted a place. The question of whether the odor is freely radiated or only given off at close quarters or when part of the plant is crushed must be taken into account. One can forgive *Lilium szovitzianum*, but a blow from the Crown Imperial stirs thoughts of banishment and the writer would give no quarter to *Phuopsis* (syn. *Crucianella*) *stylosa*.

Some perfumes are better at a distance than at close quarters, and of these the Giant Lily provides a good example. In the evening, when twilight deepens in the wood and all the air is still, a large group of these fine flowers makes its existence pleasant felt a considerable way off, but close to them, the scent is almost overpowering.

A scent should not be condemned solely on the evidence of its name. The fragrance of May-scented hedges in Spring need lose none of its pleasant associations because the chemist declares it to be due to the same substance as that which resides in "good red herring."

With the great number of sweetly scented plants which have long been known, it is natural that scented gardens should have been thought of and written about often enough. In many cases, however, they either represent a compromise between ornament and odor or else they give pride of place to herbs—those interesting aromatic plants around which hang so much history and romance. There is still room for the application of this purpose of the principle which guides the purely ornamental disposal of flowers.

The arrangement of color schemes which shall afford harmonious combinations over as long a period as possible requires taste, judgment and a knowledge of the plants employed. Still greater scope for originality and individual expression lies in the arrangement of plants to produce pleasantly blended scents through as much of the year as possible and changing with each turn of the weather-vane. "Awake, O north wind and come, thou south; blow upon my garden that the spices thereof may flow forth." That, even in this country, something could be done toward the realization of such an ideal is shown by the number of plants there are to draw upon if scent is the only requirement. Shrubs

and herbs, annual and perennial flowers, would all be included so long as their odor was radiated.

The subject is a big one, but its complexity is one of its attractions. Among the points to consider would be not only the nature and amount of ground available, but also the relative strengths of the scents of different plants, the time of day or year at which they were given off and the effect of mingling two or more. It is a blend, not a mere mixture, that is desirable, for, if we accept the theory that scents are conveyed to our perception by vibration, it is easy to understand that, like color or sound, they are liable to discord. It is not the odor within the sun-baked tents at Chelsea that attracts the crowds.

Among the host of applicants which spring up before the mind's eye at the call for examples, it is pleasing to see many with the record of generations of worthy service behind them. Far be it from modern gardening to scorn the flowers of the past and lavish all its favors on foreign immigrants, however distinguished these may be in certain directions. We accept, therefore, such names as those of the Wallflower, *Mazereon*, Rose and Sweet Briar, Lily of the Valley, Mock Orange, Mignonette, Lavender and Thyme—to mention only a few. Lest, however, it be thought that none of the newer introductions can hold their own with these, we would include that sweetest of shrubs, *Viburnum Carlesii*.

One of the best scent-diffusers in Spring is the evergreen shrub, *Asara microphylla*, the inconspicuous flowers of which emit a strong odor of vanilla. In September a strong and pleasant scent is given off by the handsome yellow fruits of *Cydonia Sargentii*, a dwarf shrub of great merit, also for its flowers in Spring.

The names mentioned form but a small proportion of the possible total, but indicate that provision for scent would not entail sacrifice of sight. Evergreen foliage and beautiful flowers would come in by the way and add charm to the fount of natural perfume. The emphasis is laid on the word "natural" lest some enterprising manufacturer should be encouraged to try to popularize spraying by adding synthetic perfumes to his proprietary mixtures. If that occurred one would feel disposed to exclaim: "O what a fall was there, my countrymen!"—*The Garden*.

PROTECTING BUSH FRUIT FROM BIRDS

LAST Winter my Gooseberry and Currant bushes (not black) suffered badly from the depredations of birds, which stripped the buds off wholesale, and not content with attacking these, did a lot of damage also to the buds of Plums and Damsons. It was late before I noticed what they had been up to, and I intend being before them this Winter. Any necessary pruning will be done immediately the leaves are off, and then the bushes will be protected with black cotton, which as far as my experience goes is the most effective agent for keeping the birds at bay. I put four or five sticks around each bush, and thread the cotton from stick to stick round and across, and the operation is very simple and soon done. It needs to be taken quite near to the soil, as the birds often hop along the ground to the bush, if it be a Gooseberry. In the case of larger bushes and Plums, the cotton can be fastened from twig to twig, and if the bush be too high to reach, the reel of cotton can be thrown across from side to side, so that a number of threads criss-crossing over the bush are soon in position, with a little trouble, and it is astonishing how effective a few such threads are. It is most disappointing when the bushes had a good show of fruit buds for the next season, to go down one day and find the branches stripped bare, every bud picked out, as is often the case where the bushes are unprotected.

When pruning Gooseberries I like to cut out all drooping branches, as well as all those which cross, and leave the bush well open, instead of the thicket into which old bushes are so often allowed to develop. Not only does one get larger fruit from a well-pruned bush, but it has a much better flavor from having been exposed to the beneficial influence of the sun—to say nothing of the added comfort in gathering. Sawfly larvae having been numerous this past year, it will be a wise precaution to remove the top two or three inches of soil from under Gooseberry and Currant bushes (taking care not to injure the root), and bury it deeply, replacing it with good soil from another part. Not only will this do much to keep off the pest, but the bushes will benefit from the new soil. *Gardening Illustrated*.

HORTICULTURE IN HOLLAND

THE "Dutch Number" issued by the London *Times* on December 6, gives an admirable and complete picture of life in the Netherlands and of the industries in which the Dutch excel. The fact that the article on horticulture—under the picturesque title of "The Garden of Europe"—is by Mr. Ernst H. Krelage, the vice-president of the Netherlands Horticultural Federation, is a guarantee of its excellence, and if that article be read in connection with others in the number on the constitution of Holland and on the agriculture of the Netherlands, it becomes easy to understand why horticulture in Holland has reached such an important position. Four causes would appear to have contributed to this result, the first, and doubtless the most important, is the natural bent of the people. The addition of Dutchmen to horticultural pursuits is of no modern origin. In the middle ages, as Mr. Krelage observes, they were already famous for their skill in horticulture. During the fifteenth and sixteenth century, migrants from the Netherlands established themselves in Denmark and in this country and engrafted on the stock of local practice their specialized knowledge of horticulture. Indeed, Mr. Krelage makes the interesting observation that the horticulture of Guernsey owed its origin to the enterprise of Dutch settlers in that island. Natural proclivity and industry would thus seem to constitute the prime cause of the success which Dutchmen have achieved in the practice of horticulture. Side by side with these gifts go also those of aptitude for business and readiness in combination. Second among these causes is the instinct for or habit of specialization which characterizes both Dutch farmers and Dutch horticulturists. This specialization is seen in the localization of special forms of horticulture in special regions. Centering round Aalsmeer are the floral farms. The neighborhood of Haarlem is famous for bulb cultivation; Beverwijk is a great Strawberry growing center. The provinces of north and south Holland are the great vegetable growing districts in which are produced vast quantities of early potatoes, broccoli, cabbage, carrots, peas, beans, etc. To this form of cultivation some 62,000 acres are devoted. Fruit growing, which absorbs an equal area, is more generally distributed. The trees and shrub-raising industry is carried on in such centers as Boskoop, Naarden and Oudenschosch. Specialization in distribution, no less than in production is a characteristic of Dutch horticulture, and in illustration of this fact Mr. Krelage points out that in pre-war days the cut flowers of Aalsmeer, the island village near Amsterdam, were exported daily not only to the British, German and other neighboring markets, but also so far afield as St. Petersburg and Constantinople. The area under bulbs is about 10,000 acres, and the exports in previous years reached the enormous figures of 25,000 tons, valued, according to Mr. Krelage, at one and a half million pounds sterling. The third cause of the excellence of Dutch horticulture is to be traced to the excellent system of horticultural education which is in vogue in Holland and the excellence of that system derives to no inconsiderable extent from the curiously decentralized constitution of the country. As a result of this large measure of local government the central authority does not loom too large in education, but each district has the power of determining the kind of horticultural education which it shall receive. As consequences of this partial decentralization, local interest in horticultural education is stimulated and at the same time the excellent system of State prevention of plant diseases is rendered possible. Last, and by means least, among the causes which have led to the great success of Dutch horticulture, is the quality of the soil. Soil and climate—no less than the industry and skill of the people—enable the Dutch growers to cultivate with success, not only the more easily grown bulbs such as Narcissus, but also such difficult subjects as the Hyacinth. As a consequence of Dutch horticultural industry and of other forms of intensive farming, this small country, one-ninth the size of Great Britain and Ireland, supports a population of 212 persons per square mile as compared with 144 in the United Kingdom. Without mineral resources, compelled to import coal and also food-stuffs for man and cattle, Holland, nevertheless, continues to maintain a population larger in relation to its area than that of any other country in Europe, except Belgium. Nor is the industry of the Dutch content with the cultivation of the land which is already available; it extends also to great schemes for reclaiming yet more land from the sea and at the present time a project is on foot which, when completed, will add a new and fertile province to Holland. By constructing a system of dykes in the Zuider Zee it is expected that 500,000 new acres of rich loamy land will be reclaimed.—*The Gardeners' Chronicle* (British).

THE PRUNING OF ESPALIERS AND WALL TREES

IT is, and long has been, the practice to treat wall trees and espaliers in a way which cannot very well be described by another word, than "barbarous." Many operators with knives or with secateurs use these implements upon the trees with which they are dealing as if they were dressing a Thorn hedge. Every

shoot is rigidly cut back to an undeviating length, and when the work is completed the pruner looks complacently on the mutilated trees and congratulates himself upon the neat and tidy result of his attention. Neat and tidy it may be, but it is an entirely unnatural process. This continual cutting is a constant fight with Nature; and when Nature is persistently curbed or checked she has her own methods of exacting retribution. The continued repression of any fruit-tree inevitably leads to infertility, or, at least, to light and indifferent crops. It may—nay, it does—result in canker and in disease. If, when there is room, this pinching and pruning were dispensed with, and trees were permitted to grow freely, not only would the crops be surer year by year, but the productiveness of the trees would last for a longer period. Regular and moderately heavy crops would balance the tree, and prunings would practically cease to be necessary. No doubt at times there might be occasional over-exuberant shoots, but if these were taken in time and pinched back, the sap would be diverted to other portions of the tree where it would be of more service. Further, the act of pinching would cause the strong shoot to break most likely into two, and this in itself would prevent or at the least discourage grossness.

It cannot be denied that there is a great lack of thought in the method usually adopted in dealing with wall trees and espaliers. At first, certainly, it is not wise to let a tree, which must ultimately be restricted to a given space, grow away too freely. The branches ought to be formed by degrees, and this ensures a uniform number of young growths—afterwards the fruit-bearing spurs—along their entire length. Bare spaces among the branches can never afterwards be filled—at all events, filled satisfactorily—but when spurs are too thickly disposed along the branches it is quite an easy matter to reduce their numbers. Thinning the spurs may, indeed, become necessary in order that those retained may receive sufficient light and air. Not only so, but when spurs are too thick both air and light are prevented from reaching the main branches, and these require both, equally with the spurs.

It is all very well for the advocates of close pruning to point to the fine fruits which are produced under their system of training—or, rather, of pruning. Even they, however, will not deny that these fine fruits are few in number, and that year in, year out, their trees do not bear even these few fruits consistently. It is not a matter of conjecture, but has been proved, that a tree planted, say, six or eight years, and given its head, will bear treble the fruit that an espalier planted at the same time and rigidly pruned will do. It is one of the signs of the times that this fact is now being generally recognized, and the oncoming generation of gardeners will, I feel sure, use the knife with more caution and with greater thoughtfulness than we their predecessors have done.—*Gardening Illustrated*.

PLANT FERTILIZATION FROM THE AIR

THE subject of manuring crops or plants is always interesting to the horticulturist, amateur or professional. Those of us who can look back half a century have noted the rapid strides that have been made in the science of supplying to each crop or plant the exact chemical that is most needed for its growth and structure, but this has hitherto always been accomplished through the roots.

Organic manure is unlikely to be superseded as a base, for it supplies the humus in the soil, the disintegrated product of decomposed straw, leaves and vegetable refuse. So far chemistry has not produced any synthetic equivalent for this, so that its value remains unimpaired.

The air is, we know, very rich in nitrogen, but it cannot in its gaseous state be absorbed by the plant. A small portion is, by the agency of rain and moisture in the air, converted into ammonia in the soil and is quickly seized upon by the roots of plants.

Carbonic acid gas, always present in our air, can be, and is, absorbed and broken up above ground by the plant itself. The green leaves of plants are in themselves a wonderful laboratory wherein the chemical reaction takes place, the carbon being absorbed by and into the structure of the plant, while the oxygen is liberated, and it is of this wonderful process of collecting materials from the air that I wish to speak.

The normal quantity of carbonic acid gas or carbon dioxide in the air is somewhere about 0.03 per cent, a minute quantity, and yet if this is much exceeded the effect on animal life is disastrous and a large quantity is absolutely fatal. It appears, however, from experiments that plant life will thrive and flourish luxuriantly in an atmosphere impregnated with five or six times the normal quantity.

As far back as 1902, Messrs. Brown and Escombe published a paper giving the results of experiments in using carbonic acid gas on growing plants by raising the content of the carbonic acid in the air of the glasshouse to 11½ parts per 10,000, but the results were not satisfactory. There is no mention of the gas being purified, so that impurities present in the gas would account for the misleading results.

Later Demoussy also made experiments with an increased amount of carbonic acid in the air, and found that of sixteen different kinds of plants grown in a mixture of 15 parts carbonic acid in 10,000, all except one showed improved condition to an average value of 40 per cent.

Experiments by Kisselew, where the gas was purified and the carbonic acid content raised to 17 parts per 10,000, the plants so treated, as compared with the controls, showed thicker stems, denser foliage, larger flowers, earlier flowering and increased weight, while the species of plant that failed to respond to the Demoussy treatment was no exception to the general improvement.

I have just had the pleasure of a long conversation with a friend who has been permitted to inspect these last experiments, although I believe at the place I have in mind the experimental stage is passed and the process of "gassing" plants is being put into commercial use in a most satisfactory way. Certainly, if all he tells me is true—and there appears no reason to doubt—the results are not only extremely interesting, but of the highest value both for private and commercial work.

Briefly, the process of fertilizing plants from the air and increasing the crop from 150 to 300 per cent, as is claimed, consists of purifying carbon di-oxide as it comes from the greenhouse fire or stove, lighted for the purpose, and passing it, after purification, into the glasshouse by means of a perforated pipe. The plants readily absorb the gas and respond with increased leaf, fruit and flower.

As carbon di-oxide is a waste product and is belched forth in millions of cubic feet from a multitude of chimney stacks; as, moreover, the purification is, I understand, a simple and inexpensive matter, there seems a great opening for the development of this process. My friend tells me, in addition, that where the gas is used in glasshouses no insect life survives, the plants are fumigated as well as fertilized.

Carbon di-oxide being so much heavier than air, the process can be carried on quite well outdoors. The gas falls to the ground and is carried slowly among the crop.

The experiments have not, unfortunately, been carried out in this country, but now that the results are known and vouched for, there should be no hesitation in applying tests to demonstrate that crops and plants will live and thrive and yield greatly increased crops in an atmosphere that is impregnated with large quantities of carbonic acid gas, a waste product that can be had for nothing but the cost of purification and delivery.

I understand that the matter is being laid before some of our big commercial firms and various research stations throughout the country. At the same time, if some enterprising amateur would install the process and allow its practical working to be thoroughly tested much good might accrue, as in times of trade depression every ounce of help is valuable. It would indeed be an achievement if by means of a waste product the yield of glasshouse or garden could be largely increased and at the same time the air we breathe kept free from a harmful gas liberated by every fire that burns.—*The Garden.*

THE HEPATICAS

BEAUTIFUL Spring flowers in the mountains, copses, and woodlands of North America and some parts of Europe, though not of the British Isles, these are treasures with which to adorn our gardens. Harbinger of the days that are to come, their charming flowers appear with the advent of the New Year, gradually increasing in numbers until the end of March, when they reach the zenith of their beauty. The Hepatica loves a loose, moist, leafy soil, such as the decayed matter found in the ditches of old woodlands, and a site screened from bright sunshine, such as is provided by Summer-leaving trees or the shade of a wall, evergreen trees being too heavy and dense. Given these conditions, the plants will not only flower profusely but will seed freely. The favorite haunt of the Hepatica appears to be the southern Oak woods of the Alps, where it is protected from the glare of the sun. It is also said to be one of the mountain plants that creep nearest the Mediterranean wherever the hills approach the sea. I grow them at the foot of easterly walls and beneath thinly furnished pergolas, positions in which the roots are cool and protected from direct sunshine. Under these conditions they have grown into large clumps, a single plant producing hundreds of flowers. The soil being heavy, much sand, grit, and leaf soil were added when the plantations were made. After a number of years, some of the latest plants show signs of exhaustion, and I find it necessary to lift and divide them, this being done in early Autumn. Although blue, lilac, and purple-flowered varieties predominate, we have white, both single and double, pink, and deep red, also single and double, all producing a charming effect, whether in the shaded border, cool rock garden, or other position suitable to their requirements.

On cold and damp soils the Hepatica loses its leaves in Winter, whereas in well-drained soils the leaves are to a considerable extent retained. In order to keep them cool in Summer, I place

flat stones about the plants. A prettier way is to plant dwarf Sedums and Rockfoils among them, as these add additional charm. The first and most important point in the culture of these exquisite harbingers of Spring is to find the site and soil most suitable to their requirements. This should be fairly deep, a these little plants are deep rooters, well drained, and with which has been incorporated a goodly quantity of grit and decayed leaf-mould, among which the masses of roots may ramify freely, and in which the plants may remain undisturbed for a number of years. Scatter thin top-dressing of soil over them each Winter when the leaves of overhead trees have fallen. The leaves thus buried will then become excellent material for the plants to feed upon. It is remarkable the quantities of flowers a single clump will produce, and this at a time when the majority of plants are at rest.

Raising from seed is very interesting, as by this method one is never quite sure as to what the result will be. This element of uncertainty is, therefore, very fascinating, and we look forward to new and various color shades. The seed should be sown as soon as ripe in boxes of sandy soil, placed in a cool, shaded frame, or even in the open air, with a slate over it to keep down moisture. Some of the seeds will be found to germinate early, whereas others will not do so until the following Spring, when the seedlings should be pricked off singly into good soil and grown on freely.

The Great Hepatica (*Anemone Hepatica angulosa*), from the hills of Transylvania, is a strong-growing plant, from 6 inches to 10 inches in height, and is the first to bloom, the lovely sky-blue flowers being as large as a crown piece. This handsome species spreads by means of long underground stems, and has large, pale green, five-lobed, woolly leaves. It is a very beautiful and choice plant, which with me, however, takes longer to become established than the common Hepatica. *A. H. angulosa atrocerulea grandiflora* is an improved form of the Great Hepatica, with flowers of deep purple-blue. These are larger than those of the type, and the plant is more vigorous.

A. H. angulosa lilacina is a charming plant, with pale lilac flowers, the broad petals overlapping. It is also said to flower earlier than the type in some parts, but with me this is not so. *A. H. angulosa alba* produces large single white flowers, and should be included in every collection.

The common Hepatica (*A. H. triloba*) is less vigorous than the Great Hepatica, rarely reaching more than 10 inches in height. There are several varieties of this, but, to me, the type is the most beautiful of them all. The single flowers are produced in the wildest profusion upon mature plants, these varying in color from pale lavender to sky-blue, each little plant a cushion of bloom. It is nothing unusual for a single plant to produce over a hundred blooms at one time, each crowned with a tuft of white anthers; their effect when grouped in large numbers is both striking and superb. I grow hundreds of these plants and their amazing beauty each year as this sea of blue arises above the cushions of unfurling leaves is one of surpassing charm. *A. H. triloba alba* is a pretty and welcome plant. The numerous anthers, being of a bright reddish color, form a pleasing contrast to the whiteness of the petals. There is also a double white form of this which is attractive, but at present rather a scarce plant.—*Gardening Illustrated.*

THE LATE JUDGE MAREAN

(Continued from page 43)

And now that the last wonder has been wrought, the tools laid aside, there is solace in the thought that in great and little gardens throughout the land the beautiful flowers, called into being by his love and skill and prepared for the future development, will bud and unfold, like the page of an immortal book, carrying his name down the years in honor and affection, thankful for his loving foresight to carefully arrange for the continuation of his great work, following his principles in every way.

And even the earth will hold him tenderly who wrought it to such noble ends.

To the family of Judge Marean we extend our tenderest sympathy. Their mourning is widely shared, for the gentle philosopher of "Daybreak" counted his friends among all classes, and his unfailing kindness to all who sought his advice or laid claim upon his time will not soon be forgotten.

Sunshine was he in the Winter day;

And in the mid-Summer coolness and shade.

JOHN SCHEEPERS.

National Association of Gardeners

Office: 286 FIFTH AVE., NEW YORK

President—Robert Cameron, Ipswich, Mass.
Vice-President—John Barnet, Sewickley, Pa.

CLEVELAND CONFERENCE POSTPONED

The proposed gardeners' conference to be held in Cleveland during the National Flower Show has been postponed because of the unfortunate condition of not being able to use the new city building on the dates planned, and the necessary removal of the show from Cleveland to another city. Indianapolis has been selected as the city for the show. The sudden change has naturally upset all plans of the garden fraternity, but the hope has been expressed that an opportunity will soon present itself when a gardeners' conference, under the auspices of the members of the association located in and near Cleveland can be held.

OPENINGS FOR APPRENTICES

The Secretary's office has quite a number of applications from young men in different parts of the country who are eager to take up the work of gardening as apprentices. These young men have had a fairly good education—grammar school and one or two years of high school. Some have had no practical experience in gardening, but others have spent Summers in gaining a little knowledge of gardening. All express a desire to take up this work as their life's profession, and the Secretary

would be glad to learn of any one who can accommodate one or more of these young men as apprentices.

BOOST YOUR ASSOCIATION

Won't you help our association by talking of it among the gardening fraternity in your locality? From time to time recently, the Secretary's office has had more than the usual number of visits from gardeners who remark that while they had lived in such and such a place for some time they had only just learned of the existence of the association.

In your neighborhood there are surely gardeners who would be interested in the association if some one called their attention to it. When you meet a gardener who is not familiar with the N. A. G. tell him of its purposes, and endeavor to enroll him as a member. Increased membership means increased co-operation among the gardeners in this country, and it is only through co-operation that the association can carry out its aims.

JOSIAH TAYLOR MAREAN

Horticulture has sustained a distinct and grievous loss in the passing away at the age of 79, of ex-Supreme Court Justice Josiah T. Marean, of Brooklyn, N. Y., and Greens Farms, Connecticut. He died on Wednesday, February 8th, at Winter Park, Fla.

The burial services were conducted from the First Presbyterian Church, Brooklyn, N. Y., on Monday, February 13th. A large number of Supreme Court Judges were in attendance as pall bearers including the following: Abel E. Blackmar, Presiding Judge of the Appellate Div.; William J. Kelley, David F. Manning, Edward Lazansky, Norman S. Dike, Almet F. Jenks, Augustus Van Wyck, Lester W. Clark, Edward B. Thomas, Martin W. Littleton, James Shevlin, John E. McCooey, James D. Sessenvan, Stephen S. Baldwin.

JAMES C. GARDINER

The Secretary has been requested to make mention of the death of James C. Gardiner on December 23, last. At the time of his passing away, Mr. Gardiner was superintendent of Millcrest Farm, Gibsonia, Pa. Mr. Gardiner was well known in Sewickley where he had been employed as head gardener for nine years on the G. H. Singer estate.

AMONG THE GARDENERS

The Secretary has received a letter from Charles R. Waugh of Santa Barbara, Cal., announcing his return from an enjoyable trip to Scotland, and expressing the keen interest he had in the New York convention.

Mrs. John Scheepers, after a severe illness of more than two months, is now slowly gaining on the road to recovery.

THE ASSOCIATION AT THE NEW YORK SPRING FLOWER SHOW

The National Association of Gardeners has again taken space at the New York Spring Flower Show, which will be held at the Grand Central Palace, March 13 to 19. The publicity which came to the association through its booth at last year's show made it worth while to engage space again, especially so as the estate owners themselves are actively interested in the success of the International Show for 1922. The same desirable location which the association occupied last year was secured again.

Throughout the entire show the booth will be open to receive estate owners and others who are in any way interested in the profession of gardening, and in the activities of its national organization. Those in charge will be glad to give information on any subject relating to the gardening profession and to the employment of trustworthy, reliable and efficient gardeners.

INTERNATIONAL FLOWER SHOW

New York, March 13-19

NATIONAL FLOWER SHOW

Indianapolis, March 25-April 1

LOCAL SOCIETIES

NASSAU CO. HORT. SOCIETY.

The monthly meeting of this society was held on February 8 in Pembroke Hall, Glen Cove, L. I.

President William Milstead occupied the chair. A petition for active membership was received from Andrew Johnson of Roslyn. Frank Watson, Thomas Meeth and Thomas Scott judged the exhibits and their decisions were as follows: 6 tomatoes, 1st, J. Rowler; pot of *Pseuda Malva*, 1st, James McCarthy; a vase of sweet pea "Rose Queen" exhibited by Peter Smith was awarded a Cultural Certificate.

Exhibits for March 8 meeting will be 12 mixed roses, pot or pan of tulips, and 12 carnations.

ARTHUR COOK,
Cor., Sec'y.

CLEVELAND HORT. SOCIETY.

The regular meeting of this society was held February 9.

The failure of the National Spring Flower Show to be held in Cleveland was the main discussion and the inconvenience it was putting the gardeners to. It was decided to hold a small exhibit among members, with a little entertainment the latter part of March.

There were two beautiful specimens of white cyclamen, plants that had been held over from last year, in 8-inch pots, exhibited by R. P. Brydon, for which he received a Certificate of Merit. He also exhibited some very well-grown, colored freesias for which a Cultural Certificate was awarded. A pot of *Asiatica (elecia) celestis*, exhibited by L. B. Webb, was very well grown, and received a Cultural Certificate.

C. Irish, a prominent Cleveland arborist, gave an interesting talk on spraying which was greatly appreciated by members.

ST. LOUIS ASSOCIATION OF GARDENERS.

The January meeting of the above association was held at the Forest Park Greenhouses on January 4. After a short business session, the evening was given over to general jollification and exchange of ideas among those present, the object being to give the members a chance of becoming better acquainted and to advance good fellowship. The evening was thoroughly enjoyed by all present.

The February meeting was also held at the Forest Park Greenhouses on February 1. At this occasion A. Vendereem of the Westover Nursery Co. delivered an address on "Modern Nursery Practice." Mr. Vendereem covered his subject very fully and his remarks led to an extensive discussion on propagation and growing of young nursery stock. It also led some of those present to relate interesting and amusing experiences of their apprenticeship both in Europe and America.

L. P. JENSEN, Cor. Sec'y.

TARRYTOWN HORT. SOCIETY

The regular monthly meeting of the above society was held in Masonic Hall, January 18th, with Pres. Wilson and a large delegation of members present.

The presentation of Wm. Graham's prize was first exhibited with a beautiful plant of *Impatiens Sultana*. Among the other many good exhibits, noteworthy of mention, was an extra fine vase of carnation "Belle Washburn," staged by Wm. Graham. Horace B. Reed, manager of Fruit Farm, Conyers Manor, Conn., delivered a very instructive

SEEDS

SEED SERVICE — PLUS

FOR 121 years J. M. Thorburn & Company specialized in high-quality seeds. Their service to the American public, their quality of merchandise, their dependability is well known the country over.

For 85 years James Carter & Company of England has been supplying garden lovers everywhere with "tested" seeds under the label of "Carters Tested Seeds"—seeds selected from strong, vigorous plants, true to type and of the best strains.

We wish to announce to the American garden loving public the consolidation of these two companies. Over two centuries of seed service-ability are now united into a single organization and we are enabled to give you a service never before obtainable in this country.

Rep. Sec'y.

UNEMPLOYMENT AND HORTICULTURE

The reaction of the public schools throughout the nation to Mr. Herbert Hoover's request that they do their share towards relieving unemployment was remarkable indeed. The schools were asked to consider the problem of unemployment from two different angles; first, immediate relief, and second, permanent relief. The first could be touched upon by the building programs throughout the country; increased building of schools would employ thousands more men. The second is a matter of education; it means that courses dealing with current events, economic and social problems will have to bring special light to bear upon the problems of employment.

In this connection it is somewhat heartening to feel that the nature of some of the courses given in Cleveland schools lends itself to the solution of the unemployment problem. Horticulture is a profession which has drawn upon Europe for its supply of trained men for some time. The field is calling for a great number of American young men and women. They must be trained in the public schools if a high standard, dignity and *esprit de corps* are to be maintained. Greenhouses—school greenhouses—is a very definite answer to Mr. Hoover's request. This means immediate relief for some in the construction of new and much-needed greenhouses. Then, too, as they become acquainted with greenhouse work, they are guaranteed pay for out-of-school time, thus helping out the family budget. It means a step in the direction of permanent relief in that students are trained in school greenhouses to cope with economic and social conditions through actual experiences in labor-cost problems, food production, home beautification.—*Nature Garden Weekly*.

WINTER PROTECTION OF EVERGREENS

The recent snowfall—the first of the season—weighing down as it did many evergreens, should serve as a reminder to tie up and protect such specimens as require this treatment against breakage which may occur any time throughout the Winter when the elements may be less lenient than during the past storm. Snow alone may not cause serious injury, but when accompanied by sleet, followed by continued cold weather, as was the case two years ago, more or less breakage to plants is bound to happen.

Take Hybrid Rhododendrons, for instance, where every six inches in height count and in which weak growths abound, it pays to have these reinforced with raffia or light rope or possibly sheltered lightly with corn fodder. Such plants as the *Biota orientalis*, some Junipers and Cedars, which are inclined to develop double or triple leaders, should be tied in loosely to keep their together, especially if plants are large and their disfigurement would mean a real loss. This tying in is also beneficial from a cultural standpoint for it encourages a more compact growth.

The Retinisporas will catch and hold more snow than the Spruce, Fir and Pine class and so should be protected, if large or

Some Interesting Novelties in Trees, Shrubs, Small Fruits, etc.

through the
Arnold Arboretum
from China and Japan

- Elscholtzia Stauntoni, Heather Mint.** In September a mass of pale lavender flowers all buzzing with bees. Mint family. 2' high, \$1.00 each.
- Evodia nuphense.** A Linden like tree from China. 3-4' high, \$1.50 each, \$10.00 per 10.
- Halesia carolina monticola.** Grows as a straight tree 80' high, or a many stemmed bush-shaped tree like the others. 3-4' high, \$2.00 each.
- Juniperus littoralis.** Used by the Japanese for holding sand dunes. \$1.00 each, \$7.50 per 10.
- Malus Arnoldiana.** White flowers, deep red cherry sized fruit that tastes as good as cider when frozen and decayed. 4-5' high, \$1.50 each; \$10.00 per 10.
- Morus acidosa.** A bird feeding plant. Most people consider the mulberries too sweet. This one may suit. 3-4' high, \$1.00 each; \$7.50 per 10.
- Philadelphus magdalenae.** One of the new Philadelphus. 3-4' high, \$1.00 each; \$7.50 per 10.
- Rosa Hugonis, Father Hugo's Rose.** A welcome addition to the shrubs. Big, round bush of healthy foliage with bright yellow flowers similar to, but earlier than, the Persian Yellow. \$2.50 each, \$22.50 per 10.
- Sorbaria arborea glabrata.** Vigorous shrub with white panicles in mid-summer, almost as showy as *Hydrangea paniculata grandiflora*. 3-4' high, \$1.50 each.
- Styrax obassia.** Chas. A. Dana's Arboretum has the only large specimen we know of. It is an old tree 14' high with circular leaves; racemes of orange, blossom-like flowers in May and coffee-like fruit. 2' high, \$1.00 each.
- Cotoneasters.** Rare and beautiful group. Some suitable as low plants for the rock garden; others as taller shrubs in the background. You can show off a collection of these all winter. Some cling to the rocks with graceful sprays of evergreen foliage and coral berries.
 - C. Zabelii.** 2' high, \$1.50 each; \$10.00 per 10.
 - C. divaricata.** 2-3' high, \$1.00 each; \$7.50 per 10.
 - C. Dieckiana.** 2-3' high, \$1.00 each; \$7.50 per 10.
 - C. floribanda bullata.** 2-3' high, \$1.00 each.
 - C. rotundifolia.** 1' high, \$75 each.
 - C. Salicifolia.** 4" pots, \$1.00 each.
- Crataegus (Hawthorn).** We have 10 species of the best from Highland Park, Rochester. Welcome in your shrubbery as hedges or as little trees.
 - Crataegus Genesensis.** 2' high, \$1.00 each; \$7.50 per 10.
 - Crataegus Dunbari.** 2' high, \$1.00 each; \$7.50 per 10.
- Cornus florida rubra.** Red flowering dogwood, 5' high, 50 to 100 flower buds, \$6.00 each.
- Cornus kousa.** Beautiful Japanese tree. Much later than the above. 8' high, \$6.00 each; \$50.00 per 10.

Elscholtzia Stauntoni

- Cornus Dunbari.** A hybrid of Japanese and American Dogwood. A small growing tree, having handsome white flowers in July. The branches are red. 5-6', \$3.50 each.
- Cornus paucinervis.** Low growing cornel from China. White flowers, black berries. \$1.00 each.
- Viburnum Wrightii.** Described and named for the botanist of the Perry expedition. 2' high, \$2.00 each.
- Viburnum opulus var. xanthocarpa.** Yellow fruited highbush cranberry. \$1.50 each.
- Xanthoxylum schinifolium.** Chinese relative of the Toothache Tree. May make a good hedge. Foliage glossy with fragrance of paragonic. 2-3' high, \$1.50 each; \$10.00 per 10.
- Syringa reflexa.** A new lilac from China with hanging racemes. 2-3' high, \$1.50 each.
- Picea Korym.** New species from China. 18-24" high, \$5.00 each.
- Photinia villosa, Chinese Christmas Berry.** Red berries in November. Flowers like Shadbush. 3' high, \$5.00 each.
- Symplocos paniculata.** Turquoise Berry. Very rare. Berries are robin's egg blue. \$7.00.
- Ilex crenata.** Japanese Holly. Boxwood-like foliage. Just right for woods or foundation planting. 3', \$5.00.
- Vaccinium corymbosum.** Swamp Blueberry. Delicious fruit. Oak-like branches, red bark in winter. 4' x 3' high, \$3.00 each.
- Ilex opaca.** American Holly. 2' high, \$4.00 each.

TIME-SAVING TREES

Thirty years ago we started to grow time-saving trees, with roots to guarantee them to grow satisfactorily. Now they are ready.

Write to us about the rare plants you want. Come to the nursery and see the rock garden. Send for "Home Landscapes" and "Home Landscapes," Commuters' Edition.

Pools with Water Lilies

These lovely flowers show many distinct colors, although most people know only the common, many white variety. There are crimson, purple, blue and yellow Water Lilies that

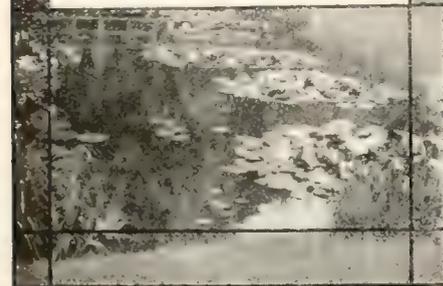

Are a Source of Delight

to every gardener who loves the unusual, and who is looking for plants that will lift his garden out of the ordinary.

My Water Lily Booklet for 1922 tells how to grow these flowers in pools or tubs, and describes the best sorts for general culture. Sent today for a free copy.

WILLIAM TRICKER

664 Forest Street, Arlington, N. J.

considered valuable enough to warrant the expense of protecting. With small plants an inexpensive and satisfactory method is to have a man beat the snow off before it becomes frozen on or weighs down the plants. Large Box Bushes are too valuable to permit being disfigured by heavy snow or sleet and bracing the branches from within with rope is recommended. In very large specimens, where the character of the branching is too weak to depend upon each other for support, it may be necessary to use poles—Cedar or otherwise—placed either within the bush or four placed around the outside and connected by rope.—*Florists' Exchange.*

The lettuce to me is a most interesting study.

Lettuce is like conversation; it must be fresh and crisp; so sparkling that you scarcely notice the bitter in it.

Lettuce, like most talkers, however, is apt to run rapidly to seed. Blessed is that sort which comes to a head, and so remains, like a few people I know, growing more solid and satisfactory and tender at the same time, and white at the center, and crisp in their maturity.

You can put anything (and the more things the better) into salad, as into a conversation, but everything depends upon the skill of mixing. I feel that I am in the best society when I am with lettuce. It is in the select circle of vegetables.—*Contributed.*

Lettuce, like conversation, requires a great deal of oil to avoid friction and keep the company smoothly. Sprinkle on olive salt, a dash of pepper, a quantity of mustard and vinegar for all occasions, but be sure that you will notice no sharp contrasts, and a trifle of sugar.

The 1922 Ten-Ten Book Is Ready for You

This new Ten-Ten Book has all the good points of last year's with a lot of new ones beside.

Again we've listed the ten best of everything for garden use.

You can make your selections without a lot of fussing through arm-long lists.

Both common and botanical names are given, with just the description and prices you want to know about.

Here is a list of just a few of the headings:

1. Ten Annual Flowers for Cutting.
2. Ten Annuals for Dry, Sunny Spots.
3. Ten Perennial Seeds for Spring Sowing.
4. Ten Hardy Phloxes.
5. Ten Plants for Home Decoration.
6. Ten Plants for Paved Walks.
7. Ten Shrubs for Hedges and Boundary Planting.
8. Ten Evergreens for Foundation Planting.
9. Ten Choice Apples.
10. Ten Choice Peaches.

Send for your copy of the Ten-Ten Book now; it is free. Then order early.

So. Zanesville, Ohio

THE GREENHOUSE MONTH TO MONTH

(Continued from page 52)

post of mushroom bed manure, a little sand and moss; divide the rhizomes into moderate sizes and place in flats. Cover them with the compost but do not water; the moisture in the rose house will give them a good start. This is far better than starting them by the usual method in dry pots.

The next batch of achimenes can be started in baskets.

Clean off the sour soil of carnation beds, gently stirring the surface, and give a fair sprinkling of bone flour. Top dress with one inch of fine loam and well rotted horse manure, and you will realize the benefit to the plants as the days lengthen and the sun strengthens.

Repot into three-inch pots any 'mums that require a shift. Do not allow any check or the buds will be developed from stunted plants and their season interrupted. Keep them very cool, 40 degrees at night and day, if possible, is desirable. If other plants are grown in the house, they must be subservient to the 'mums, or the latter will be ruined. The last batch of cuttings should be inserted this month and the old stock thrown out to make room for the new. Fumigate regularly to keep clear of aphids.

Celosia spicata is a subject useful for house decoration, easily raised and will withstand draught and dust better than ordinary kinds.

Lantanas and Bouvardias that are rooted in sand should be potted and grown along in gentle heat. The weeping Lantana is a fine specimen for hanging baskets or pans.

The sweet peas should have a good mulch of sheep manure and loam, equal parts. Remember the best sweet peas or rather the earliest are better if sown in pots in

March in a temperature of 55 to 60 degrees. They will germinate in ten days. Grow them along gently in the same temperature until weather conditions are suitable for their removal to cold frames.

Give the last batch of cauliflowers a dose of nitrate of soda, a very light sprinkling, or a watering of a teaspoonful to a gallon of water will do nicely.

THE NEPHROLEPSIS CHART

(Continued from page 46)

their cultivation. For example in the labels of the various *Nephrolepis* forms, the following general method is used:

Boston Fern	Boston Fern
Mutation of	John Scott
<i>Nephrolepis exaltata</i>	Roosevelt Fern
Horticultural	Mutation of
Pierson Fern	Boston Fern
Mutation of	Am. Rose & Plant Co.
Boston Fern	Whitman Fern
F. R. Pierson	Mutation of
Scott Fern	Pierson Fern
Mutation of	Henry Barrows

In connection with the collection of *Nephrolepis* forms the study is still being carried on and the writer will very much appreciate any information as to new forms or facts about old forms which may be contributed.

THE HOUSE FAMOUS for LAWN GRASS SEED

Our Motto: Reliable Seeds and Prompt Service

Lawn View of Private Estate Sown with Burnett's "Special" Lawn Grass Mixture.

MANY OF THE MOST BEAUTIFUL LAWNS OF THE LEADING PRIVATE ESTATES IN AMERICA, WERE SOWN WITH BURNETT'S FAMOUS GRASS SEED MIXTURES

BURNETT'S "SPECIAL" LAWN GRASS MIXTURE

The above mixture is made from our own formula, and composed of grasses specially adapted for the purpose of producing turf which retains its rich green color and velvety appearance throughout the entire Summer and Fall. In making up this high grade mixture we are

careful to use only the very finest quality of all the most desirable dwarf evergreen *re-cleaned* grasses, free from chaff and weeds, which thrive well on any soil, thus ensuring a beautiful and permanent lawn.

Price: Qt. 35c., pk. \$2.50, bushel (20 lbs.) \$9.00

BURNETT'S "KILLARNEY" LAWN GRASS MIXTURE

The above Lawn Grass Mixture "Killarney" is composed of a combination of the very finest European grasses and fescues, the highest grades possible to procure, and specially adapted for this climate. This mixture weighs 25 lbs. to the measured bushel, and is composed of all solid, re-cleaned seeds of the highest germina-

tion. Therefore, owners of large estates requiring a permanent sod and everlasting lawn should by all means use this high-grade mixture. We can recommend "Killarney Mixture," if the ground is properly prepared, to produce a turf of velvet, equal to the most famous Lawns in Europe. Give it a trial.

Price: Qt. 40c.; pk., \$3.50; bushel (25 lbs.), \$12.00

"SOW KILLARNEY AND WALK ON VELVET"

We make a specialty of *Lawn Grass Seed* and *Separate Grasses* for all soils and situations, including Golf Courses, Putting Greens, Tennis Courts, etc.

For information, write to Burnett Brothers, 92 Chambers Street, New York, N. Y. For seed, 1 bushel, 25 lbs. net (1.457 square feet), 4 to 6 weeks in advance of sowing. For seed, 1 bushel, 25 lbs. net (1.457 square feet), 4 to 6 weeks in advance of sowing.

ANNOUNCEMENT

We are now accepting orders for Judge Marean's famous Dahlia creations for Spring delivery. Judge Marean has passed on, but his Dahlias will live after to immortalize him, and carry his name down to posterity.

As was his expressed wish, the distribution of his Dahlias will be carried on the same in every way as heretofore.

We consider it a compliment to us that our business was so satisfying to him that he left it to us to continue his work.

We have in the past thrown our strength, energy and enthusiasm into the task to fittingly introduce and disseminate his Dahlias; now this sacred trust has been left to us, we must still do more, if possible, particularly to protect those Dahlia enthusiasts who wish to have in their collection a few of the wonderful varieties created by the Judge.

It is therefore that we state, that we are in complete control of the original stock of the Marean Dahlias as well as of undisseminated novelties, seedlings and the seed he gathered last season from his most magnificent varieties.

We offer and supply only strong divisions, taken from clumps that have produced fine, perfect plants last season. *No propagated plants or roots thereof will be offered by us.* This original stock is only available through our firm, with the exception of one concern, the Charles H. Totty Co., whose orders shall be filled by us from the original stock. We have made no such arrangement with any other concern or person.

For lists please see previous issues of this magazine, or ask for our illustrated catalogue.

These Dahlias will always be offered to the public on their record and our assurance of their merit, and if at the end of the season any purchaser is dissatisfied with his purchase and will return the clumps and all their increase, cuttings or other propagation, transportation paid, with an affidavit of its identity, we shall return the price, though if the plant has failed to make good it will not be the fault of the plant but of its culture.

All Dahlia lovers are cordially invited to see them blooming at

"DAYBREAK," GREENS FARMS, CONN.

JOHN SCHEEPERS

522 Fifth Avenue

New York

ACHIEVEMENT commands respect, especially so when accomplished by long years of persistent, faithful effort.

Father Time has ticked off thirty summers since Antoine Wintzer set face to the task of improving the Canna. Colors borrowed from every bird of brilliant plumage except the blue bird, and like dream clouds at sunset—with a refinement unexcelled by orchids. Four o'clock every morning used to see Mr. Wintzer moving among his Canna pets abloom, and going through the marriage ceremony with carefully chosen mates. Now he does his hybridizing indoors where the bees do not bother. A record of first prizes at all the leading exhibitions, international and otherwise, but faintly reflects the triumphs year after year.

Those who remember the old-fashioned Indian shot plant with its puny head and narrow petals, and seldom in any other color of flower than red, will be much impressed with the vast changes that thirty years have wrought. Flower heads certainly seven times as large, with beauty and variety increased to a greater degree; and by far the largest proportion of new varieties in this country during the past fifteen years have come from the undersigned, the home of "Good Luck Cannas."

Mr. Wintzer is the originator, and the Conard & Jones Company the introducer of such varieties as "The President," Mrs. Alfred F. Conard, City of Portland, American Beauty, Statue of Liberty, Wintzer's Colossal and of Snow Queen, Flag of France and a host of others.

By all means send for their catalog and get complete information.

The Dreer Dozen Hardy Ever-Blooming Hybrid-Tea Roses

THIS collection of well tried standard varieties is known to every Rose fancier as a most satisfactory selection of varieties, either for garden decoration or to supply an abundance of extra choice flowers to cut throughout the summer and fall months. All are extra strong, two-year-old plants, prepared to give immediate results.

CAROLINE TESTOUT—This is the Rose that has given Portland, Oregon, the name "The Rose City." It will be found equally valuable in any garden. A large, full globular flower of a bright satiny-rose; very free and fragrant.

DUCHESS OF WELLINGTON—Intense saffron-yellow, stained with deep crimson, fairly full flowers and particularly beautiful in bud form. Delightfully fragrant.

HOOSIER BEAUTY—Beautiful, well shaped long buds and large full flowers of an intense, rich, dazzling crimson-scarlet. Very sweet scented.

JONKHEER J. L. MOCK—Very free on long stiff stems. Large size and of perfect form. Deep imperial pink, the outside of the petals silvery rose-white.

KAISERIN AUGUSTA VICTORIA—Splendidly formed flowers and buds on long stems. Soft pearly-white with just enough lemon in the center to relieve the white. Very fragrant.

KILLARNEY BRILLIANT—An improvement on Killarney, being larger and more double, also more intense in color, which is a rich glowing shade of rosy-carmine; fragrant.

LADY ALICE STANLEY—A gem and greatly admired by everyone. Perfect in form, color, size, freedom of bloom and fragrance. Color a beautiful shade of coral-rose, center shading to flesh-pink with deeper flushes.

LADY URSULA—Of vigorous erect growth, a remarkably healthy grower under all conditions. Flowers large and of good form, with high center produced on every shoot. Color a distinct shade of flesh-pink; tea scented.

LOS ANGELES—This is by all odds one of the finest Roses ever introduced. The growth is very vigorous and it produces a continuous succession of long-stemmed flowers, of a luminous flame-pink, toned with coral and shaded with translucent gold at the base of the petals. In richness of fragrance it equals in intensity the finest Marechal Neil. The buds are long and pointed and expand into a flower of mammoth proportions, while the beauty of form and ever-increasing wealth of color is maintained from the incipient bud until the last petal drops. \$1.50 each.

MME. EDOUARD HERRIOT—"The Daily Mail Rose." Winner of the Gold Cup offered by the London Daily Mail for the best new Rose exhibited at the Interna-

HYBRID TEA ROSE LOS ANGELES

tional Exhibition, London, May, 1912. A most distinct and novel Rose. The buds are coral-red, shaded with yellow at base. The medium sized open flowers are semi-double and of a superb coral-red, shaded with yellow and bright rosy-scarlet, passing to shrimp-red.

RADIANCE—An ideal American bedding variety. A clean healthy grower, producing its flowers freely even under the most adverse weather conditions. In color, a brilliant carmine-pink and of good form. Truly a Rose for every garden.

RED RADIANCE—A counterpart of Radiance, except in color, which is a clear cerise-red.

Price: Any of the above except where noted, in strong, two-year-old plants, \$1.00 each; \$12.00 per dozen; \$90.00 per 100—25 or more supplied at 100 rate.

We will supply one of each of the Dreer Dozen Roses as named above for \$12.00.

DREER'S GARDEN BOOK FOR 1922 contains beautiful colored plates of new Roses and offers many new and standard varieties. Among them the greatest achievement of Pernet Ducher's, the New Yellow Rose, Souvenir de Claudius Pernet. It also offers Plants of all kinds, including Cannas, Dahlias, Hardy Perennials, Water Lilies, etc., Flower and Vegetable Seeds, Lawn Grass and Agricultural Seeds, Garden Requisites of all kinds, etc. Illustrated with eight color plates and hundreds of photo-engravings, this book makes an interesting volume which should be in the hands of everyone interested in gardening. A copy will be sent free if you mention this publication. **WRITE TODAY.**

Sheep Manure Tankage

A complete Plant Food for the **Greenhouse, Home and Garden.** It contains all the necessary elements for use in supplying plants with proper fertilizing ingredients. Sheep Manure Tankage is practically odorless and absolutely weedless. Sheep Manure Tankage is a mixture of the highest grade Sheep Manure—Bone and Vegetable Tankage. The object of this combination is to increase the lasting value of the Sheep Manure. The result of the mixture is a material that has double the value of pure Sheep Manure in improving the physical and mechanical condition of the soil. A trial will convince you. Costs no more than Sheep Manure. It is much more satisfactory.

Burpee's Asters

THE Burpee Beauty Asters are of inestimable value for cut flowers. The individual blooms measure 4 to 5 inches across and are carried on long strong stems. This distinct type of Asters was first introduced by Burpee. They bloom after the Late Branching Asters have finished blooming and before the early Chrysanthemums have come into the market. The early kinds come into bloom almost as soon as the Royal Asters and produce flowers for a long time.

—SELLING OUT—

THE FAMOUS ROSE HILL NURSERIES

We have still some great bargains in fine, large specimen *Trees*, both *Deciduous* and *Evergreen*. A great collection of *Box Trees* in all sizes, shapes and forms— not the tender varieties, but hardy and sturdy types.

Koster Blue Spruce; Retinosporas; Colorado Spruce; Douglas Fir; Weeping and Copper Beech; Rhododendrons, both hybrid and native varieties.

Also a large collection of double and single *Idas*, *Flowering Shrubs*, *Roses* and a complete list of hardy *Perennials*.

All are in prime condition, and must be sold to settle estate. The stock should be seen to be fully appreciated.

North Avenue, New Rochelle, N. Y.

Next Weygant Station on N. Y., Westchester & Boston R. R.

Lower Prices on Greenhouses

The same week that \$900 was lopped off the price of Cadillacs and \$1,200 or so on Marmons, and other cars in proportion, we made a drastic cut on greenhouse prices.

This cut was made on the top of several others, which now brings our houses down as near as possible to their pre-war prices.

These prices, you will be quick to appreciate, can only last so long as steel, cypress and glass go no higher.

The chances of their being lower are not encouraging. We sincerely believe this is an advantageous time for your greenhouse building.

The pride of possession of one of our houses, and the perpetual pleasure they so abundantly give, is out of all proportion to whatever they may cost.

For over half a century we have been builders of greenhouses.

Representative will call at your invitation. Printed matter you are welcome to.

Things and Thoughts of the Garden

MONTAGUE FREE

*"Always be merry if thou may,
For to-morrow is the world a-blay,
Have happy days as fresh as May,
Chapelet of Roses on Whit Sunday,
For such arraie ne costeth but lite."*

CHAUCER, "The father of English poetry," was perhaps the first to make mention of the rose in the written English language. Long before his time, of course, the rose occurs in literature. We read of an Arab writer of the 12th century, B. C., who tells of the Magi's Rose being "entrusted to the guardianship of a special angel." Theophrastus and Pliny made observations on roses as they knew them, and, continuing down to our own time, there has been a constant stream of information and misinformation, comment, and eulogy on the Queen of flowers. Poets have sung of the rose, gardeners and others have written reams of practical, but not necessarily prosaic, information concerning its cultivation; and, to all seeming, this will continue so long as time endures and roses blow.

In spite of widespread interest evidenced by many references to the rose in the literature of the ancients it was not until the close of the 18th century that it was honored by a book to itself. According to Miss Willmott in "The Genus Rosa": "The first illustrated book exclusively on roses is Miss Lawrance's folio volume, with ninety beautiful plates, published in 1799."

Since that time the production of books on the rose has been enormous, one might almost say appalling. There are books from nearly every conceivable angle—scientific works dealing with the description and classification of *Rosa*, practical books telling us how to grow them, and talky, talky books designed presumably to while away an idle hour.

Of scientific books, John Lindley's "Rosarum Monographia," published in 1820, is perhaps the most important of the older works. Coming to the modern times, Ellen Willmott's "The Genus Rosa" in two weighty volumes, splendidly illustrated, takes its place as the most sumptuous descriptive work on the rose that has ever been published.

One of the most readable books is "A Book About Roses," by the late S. Reynolds Hole. The genial Dean is always interesting, but especially so when writing about his favorite flower, and in this book there is much sound information agreeably spiced with witty anecdote.

"Roses for English Gardens," by Gertrude Jekyll and Edward Mawley is another extremely valuable English

publication, not only for the text, but also for the excellent photographic illustrations.

When writing of books on roses, it is difficult to know when to stop as the subject is so broad. Therefore we thought to pass on to other matters at this point, before getting any farther involved, but it would not do to omit all reference to the excellent American rose literature which, after all, so far as cultural directions are concerned, is more applicable to American conditions. We think the most informative and valuable publication on the rose is "The American Rose Annual," a serial published by the American Rose Society. This should be in the hands of all rose lovers. "Commercial Rose Culture," by Eben Holmes, treats admirably of this side of the subject. Amongst the older books, "The Rose, Its History and Culture," by S. B. Parsons, published in 1847, is interesting, as also is "The Rose," by H. B. Ellwanger.

The rose is England's national flower and England has long been famous for the excellence of its roses, whether growing in opulent ducal gardens or clambering over humble thatch-roofed cottages. Although 1921 was not a favorable year for roses in England, because of the drought, a few notes inspired by the editor and by our recent visit may not be amiss in this "Rose Number" of THE CHRONICLE.

Although Kew does not specialize to any great extent in roses, its representation of the genus is more than adequate and there is much of interest to the rose lover practically throughout the whole year. For, although there may not be blooms to see in the large collection of rose species there is always something of interest, even during the Winter, either in the form of brilliant colored fruits such as we get in *Rosa pomifera*, *R. Helena*, and *R. setipoda*, or in strange and conspicuous spines as in *R. omeiensis* var. *pteracantha*.

The garden roses, hybrid perpetuals and teas, are planted in a series of beds in the vicinity of the great palm house. In almost every case only one variety is grown in a bed and these give a stunning display when at their best. Here are many groups of standard roses, or, as they are called in this country, "tree roses," and, for a ground cover in these beds, the bedding violas are largely used.

Much could be said in favor of planting a ground cover beneath those roses whose habit of growth admits of this treatment. Those who advocate it claim that these low growing plants serve to shade the ground and thus help

keep the roots of the roses cool during the hot Summer months. Furthermore, if suitable plants are chosen their flowers will contrast pleasantly with those of the roses, provide beauty and interest when the roses are out of bloom and hide the bare ground. Of course careful selection of plants must be made for this purpose and only those kinds used which have a shallow root system, otherwise they will compete with their neighbors for moisture and food and the roses will suffer in consequence. It is advisable, also, to use those that may be cleared out annually, thus affording unhampered opportunity to fertilize and till the soil about the roses. Plants that have been recommended are the bedding *Violas* in variety; *Viola papilio*; *Myosotis* for Spring effect; and that charming Southern California annual, *Phacelia campanularia*. In the Cambridge Botanic Garden, it was customary to plant the bed containing the hybrid perpetual roses with mignonette. If the roses and mignonette should happen to be in bloom at the same time, one might imagine that the conflicting perfumes would be objectionable, but, as a rule, mignonette when sown out-of-doors, does not come into bloom until the main crop of roses is over.

A feature at Kew is the beds of hybrid perpetuals of strong growing kinds such as "Frau Karl Druschki," "Clio," and "Gustave Regis," grown under the "pegging down" system. Instead of pruning back the long strong growths, almost as vigorous as those produced by the rambles, the tips are bent over and pegged down to the ground. This system insures such a profuse display of bloom and the beds present the appearance of billowy mounds of blossom and give an acceptable variant to the usual rose bed.

The climbing roses at Kew are cared for on a simple, inexpensive, and yet effective pergola made of iron pipe with the uprights linked lengthwise and across by means of chains, thus forming a continuous line of garlands. This pergola extends for a distance of two or three hundred yards and is a ravishing sight in June when the roses are in full bloom. It is the practice to plant a strong grower and a weaker grower opposite each other with the intention that the strong grower should furnish the upright on one side and the transverse support, while the weaker kind covers the upright on the opposite side. There are many who claim that roses suffer when their branches are fastened to metal, as in this case, because of the great fluctuation in its temperature, but experience at Kew has shown that no ill effects are discernible from this cause.

The methods of displaying the roses at Kew are not stereotyped and the rose dell offers a suggestion that might be copied to advantage in many gardens. This is formed in an extensive hollow, the site of an old gravel quarry. The banks of the excavation were shaped to provide pleasing contours, and suitable soil introduced which was held in place, in a series of irregular terraces, by enormous tree stumps. The whole area, with the exception of a winding grass walk down the center, was then planted with rambler roses of various kinds, the tree stumps forming supports over which they clambered. Many of the roses have now found their way into trees which surround the site, greatly adding to the beauty of this valley. For this is indeed a valley of roses, growing in a most pleasing and natural way, with no trace of artificiality, and it presents a most attractive picture throughout the whole of the year.

There is a rose at Kew, raised from a bush that grows on the grave of Omar Khayyám, that is of great interest to lovers of the Persian poet, and calls to mind his quatrain:

"I sometimes think that never blows so red
The Rose as where some buried Caesar bled;
That every Hyacinth the Garden wears
Dropt in its Lap from some once lovely Head."

Whatever this rose may do in its native country, it refuses to thrive very satisfactorily at Kew, and, as we remember, it was always infested with green lice. A bush propagated from the one at Kew has been planted on the grave of Edward Fitzgerald, the first to translate the *Rubáiyát* into English. This interesting rose is *R. damascena*, a variety of which is used largely in the Balkans in the production of attar of roses, probably the most expensive perfume known. From this species many of our favorite garden roses have been developed.

* * *

The Cambridge Botanic Garden contains a representative collection of rose species and some of these are noteworthy, either for the size that they have obtained, or for their adaptability to some form or other of ornamental planting. In the latter group comes the Scotch rose, *Rosa spinosissima*. This, as its name implies, is tremendously spiny and it is well to wear stout leather gloves when working amongst its branches. At Cambridge a large bed was planted with this rose and many of its varieties. Although they did not present an especially striking display, yet they were interesting and possessed a quiet beauty all their own. This rose is found in the wild state in Europe, Western Asia, and China. It is perfectly hardy and is well worth growing by those who are interested in wild roses.

One of the most striking features when in bloom is an enormous specimen of *Rosa moschata*, or *R. Brunonii*. This clammers all over an Austrian pine and reaches a height of about 50 ft. with a diameter of almost 40 ft. It blooms quite freely in June, its flowers are white, and have the fragrance of musk. This species is found wild in Southern Asia and Abyssinia; but unfortunately is not hardy in the north. According to some authorities, it is also found wild in Europe and India, which gives it an extensive range in the wild state.

Incidentally, planting some of these strong growing roses so that they may clamber over old trees, is an admirable way of displaying their beauty. In Miss Jekyll's book, "Roses for English Gardens," there are many illustrations showing roses clambering over trees. For example, there is a photograph of a splendid specimen of climbing "Aimée Vibert," 15 ft. high and about 10 ft. in diameter, literally smothered in blooms; and the blush-white Avshire rose, the "Garland," provides a charming effect supported by an old *Catalpa*. And then there is a picture of the famous Banksian rose, taken on the Riviera, which shows it vigorously doing its best to smother olive trees and cypresses. One may readily imagine the glorious effect of its pale yellow flowers seen against the somber background.

In most gardens there are trees, living or dead, that could be spared for the purpose of supporting climbing roses and nothing could be more beautiful than a picturesque old tree when garlanded with sprays of fragrant rose blossoms.

There is another remarkable rose in this garden, a bush rose this time, *R. macrophylla*. It is notable mainly on account of its size, for it is over 18 ft. high and more than 25 ft. in diameter. This rose has one feature that commends it to gardeners in that it is practically spineless and does not present such a thorny problem to the pruner as do most of the roses. This is another Asiatic plant, coming from the Himalayas and China, and is a profuse and constant bloomer.

Hardy Iberis—Candytuft

RICHARD ROTHE

BOTH the annual and perennial garden species of *Iberis*—a genus of the order *Cruciferae*—on account of their usefulness for edging purposes, enjoy world-wide popularity. As natives of South Europe and Western Asia, taking kindly to our climate and conditions, they proved of easy culture and in the production

Iberis stylosa, syn. *Thlaspi stylosum*. (Courtesy of Alpinum Nymphenburg.)

of flowers they are as abundantly free as we see them abroad. Closely related to the hardy evergreen class of *Iberis*, and for this reason in European catalogs sometimes listed as such, are the two alpinines: *Æthionema* and *Thlaspi*. Though hardly known on our hemisphere they have in common with the *Iberis* a wonderful adaptability for dry wall and rockgarden plantings.

Of the hardy candytufts the well known species *Iberis sempervirens* leads in hardiness and dense bushy growth of the pure white ones. The varieties *Garrexiana*, *Perfection*, *Snowflake* and *superba*, as improved types of *sempervirens*, are claimed to be more or less larger flow-

Iberis sempervirens.

ering. Little Gem, identical with Weisser Zwerg, a dwarfy compact growing variety, is the ideal thing for sunny rockeries of diminutive sizes. All the hitherto mentioned begin to bloom in April, continuing according to latitude throughout May and part of June.

Iberis corrafolia, *semperflorens* and the purplish-suf-

fused *Tenoreana* are more adapted for the South. The same may be said of *Iberis Gibraltarica*, a stately growing species, with, at the base, woody branches and large corymbose heads of white flowers beautifully suffused with pinkish and reddish hues. Throughout the Middle Atlantic and Northern States those species need careful Winter protection and more or less sheltered positions.

Iberis Jucunda, syn. *Æthionema cordifolium*, a pink-flowering species from the Lebanon and *Thlaspi alpestre*, white; *rotundifolium*, light violet and *Thlaspi stylosum*, syn. *Iberis stylosa*, with pink corymbose heads are low-growing Alpines found in botanical gardens and in the collections of European amateurs.

Hardy candytufts are best raised from seeds planted early in Spring under glass. When of sufficient size transplant out in the open ground in garden soil, preferably sandy loam deeply dug. For enrichment use old well decomposed barnyard manure or some leafmold. Move established stock on permanent place of flowering

Iberis corrafolia.

before October 1st or early in April. *Æthionema* and *Thlaspi* appreciate slight addition of crushed or ground limestone to soil. Hardy candytufts may be also propagated by cuttings during Spring and early Summer. Being evergreens hardy *Iberis* require Winter protection, preferably leaf covering, thickness according to latitude of location.

Success in life may be nearly always measured by the amount of initiative shown in doing one's work. This conquering and elevating force must come from within, and is the development of a genuine desire to keep from becoming lost in the crowd; a will to do those things in hand as though the whole future depended upon the result. Difficult tasks become easier to the individual showing initiative, because he or she leaves the beaten path and finds a better solution, gaining at the end of the day a reward of sheer personal happiness at having accomplished something worth while in spite of all obstacles.—N. C. R. Progress.

My Indian Rose Garden

GEORGE CECIL

INDIA essentially is the land of roses. They may not be the choicest blooms; the petals have an irritating habit of parting company with the calyx; and though, in the main, they resemble the European variety, the gorgeous richness, or delicacy of coloring, as the case may be, is lacking. Still, a rose is a rose—whether it be a good or a bad specimen of its kind, and there is no gainsaying the fact that in India, from Cape Comorin to the borders of Afghanistan, they grow in profusion all the year round. And both the European and the native population glory in the possession of rose gardens.

When "stationed" in the upper part of India, where roses are almost as common as daisies are "at home," I was the happy possessor of a perfect rose garden. With its row upon row of flowering trees and bushes, its trim gravelled pathways and deep green turf, which, elastically yielding to the footfall, made walking on the most appallingly hot day a joy, it was the envy of my neighbors. But Fate, alas! conspired to ruin my agreeable "scheme of things entire," and one evening during the "rains," when the languorous air was heavy with the scent of a certain indigenous perfume which a recent tropical shower had brought to perfection, I received a "semi-official" letter and was transferred to a frontier town.

The thought of the roses, however, consoled me, for I had been told that the North was the Paradise of the rose-fancier.

Upon reaching my destination, I was driven past garden after garden gay with roses of every conceivable variety. The trees were thick with them; great bushes grew high enough to hide the stooping bent "bhists" (native water carriers) as they manipulated the goat skins containing the water which brought life to the roses; and many of the picturesque bungalows were half-hidden by the clustering crimson Rambler. As I neared the end of the journey I had visions of the rose garden which awaited me—for I made certain that my house, like all those I had seen, would be provided with so pre-eminently desirable an appendage. Judge, then, of the sorrow which filled a too confiding heart when I found myself relegated to an ugly, bare bungalow far from the outskirts of the "station," perched on a rock, and without the slightest vestige of a garden. However, I was determined to have one, even if it was only an apology for a garden; and before twenty-four hours had flown I arranged with a local "mali" to lay down innumerable cart-loads of earth and to transplant the required number of trees. In fact, the same evening all was in train; and when I awoke the next morning the rocky space round the little bungalow was several feet deep in earth—abstracted probably from the "compounds" (enclosed ground) of other "Sahibs."

By the time I had been a week in the new abode, roses galore met my grateful eye.

At first, everything went well. The roses flourished like green bay trees in the wilderness, while the "mali" (gardener) and the "bhisti" between them made the little garden a thing of joy. But trouble, alas, was brewing; a cloud no larger than a pin's point appeared on the horizon of my happiness, and soon de-

veloped to its full extent. For some unaccountable reason the roses drooped, the leaves turned a dull myrtle green, and each tree and bush withered and died. The occurrence was inexplicable, for gallons of water were daily expended on the garden, and the "mali" was unremitting in his attentions. Eventually the murder was out. It appeared that the "bearer" (colored valet) had a cousin, a ne'er-do-well, who, when not actually doing time, was active engaged in burglarious pursuits, and that, the thieving business being slack, he was anxious to find his relative employment—as my "mali." To that end he plotted and schemed as only a native can; and when the villain found that a desperate effort had to be made, stealing out in the dead of night, he calmly severed the roots of each tree. There was nothing to do but to order a fresh supply—and to pray that they would take kindly to their new surroundings.

What with the exasperating delay of the natives employed in searching for rose trees and the unnecessary time taken by the railway company in delivering a consignment from a "station" some miles away, I had to possess my soul in patience for what seemed an eternity. Most things, however, come to him who philosophically waits, and a month after the disaster I awoke one sultry day to find my garden blooming once more, while a crimson Rambler gave promise of rambling along the verandah railings. But I was once again doomed to disappointment. On returning to the flowery little fortress after putting in a week at a distant race-meeting, I discovered that the rose-garden again wore the dejected look which I had such good reason to dread; and a glance sufficed to show that the cause was want of water. Subsequent enquiry elicited the fact that, taking advantage of my absence, the trusted "mali" and "bhisti," sallying forth to the "bazaar," had spent the time in drinking deep of the wine which is so strictly forbidden by the prophet, with the result that when the rose-trees most needed their attention no water was forthcoming.

Nor was this all, for when, after infinite care and coaxing, the garden was once more got into order, one by one, each tree manifested signs of diminished vitality. It appeared that the "district" was infested by porcupines, and that when these most unnecessary animals grew tired of the varieties usually forming their repast, they were wont to make a raid on some "sahib's" garden, and to feast themselves, for choice, upon the roots of the rose-trees. In my case the mischievous brutes had, in this manner, killed every tree and shrub to be found on my little quarter acre of land.

Tired of battling against destiny, I left the garden to its own devices. And when, a month later, I found myself back in Lucknow, and in my old bungalow, I once more enjoyed the pleasures which had been mine before I left for the "station" where rose gardens can be both a joy and a snare.

Thus was destiny fulfilled.

5 Rue des Pyramides, Paris, VI.

How easy it is for one benevolent being to diffuse pleasure around him, and how truly is a kind heart a fountain of gladness, making everything within its vicinity to freshen into smiles.—Washington Irving.

Irises

GRACE STURTEVANT

THE year 1922 marks an epoch in garden irises. International Iris Conferences are scheduled by the Société Nationale d'Horticulture de France in Paris and by the Royal Horticultural Society in London during the blooming season, and the six hundred and fifty members of The American Iris Society plan to be well represented in the discussion preceding the acceptance of standards of nomenclature, classification, and description.*

If you are not already an iris enthusiast you do not yet realize what visions of delight the word "Iris" conjures, what wonderful color effects are possible when the modern irises are planted in masses with your other garden flowers. This is the month for planning and I hope that all of you have marked a generous number of spaces on your garden maps with the magic word "Iris" and that already you have dreamed over the tantalizing descriptions in the catalogs of the specialist. The iris is best planted after the flowers are past, so reserve the space, not only by marking it on your plan, but also by placing a corresponding stake in the garden itself. This late planting also permits you to visit exhibits and nurseries (the New York Botanical Garden has an official Test Garden and this year an exhibit on June 3rd), to select from the blooming plants not only the color, but the very height, or habit, that will perfect your pictured scheme.

I do not want a garden of irises *only* (a collection is another proposition altogether) but rather one where other perennials in contrast may enhance their delicate beauty of form and color; early bulbs, *Arabis* and Mat pinks with the *Korolkowii* and *Pumila* hybrids, *Phlox divaricata* and tulips with the Intermediates, Sweet Rocket and Lupins in pink and purple and white, with the later irises with here and there yellow roses, *Hugonis*, *Harrisoni*, and Persian. Sometimes the peonies and rambler roses flower before the irises are gone and then, as is the case with some of the flaming oriental poppies, we must restrict our iris colors in the interests of harmony. A garden of irises alone should be in a secluded spot, a fairy land where one can visit in its glory and then leave to the gardener until another Spring.

For distant and mass effect clear self tones in various colors are the best, markings on the falls reduce the apparent size and blended tones become a mere blur in the distance. Varieties with short, high branches that bring the blooms nearly on a level form a more solid sheet of

color. But in the garden where the flowers are within reach and generally below the level of the eye, plant those with some outstanding quality of delicate color or unique marking, of form, substance, or satiny or velvety texture. There are varieties of blended tones where thin layers of lavender and pink and yellow in varying intensities seem laid one upon another, others where two sap colors seem actually combined in the cellular structure, and many whose beauty changes with every change of light. Some are most fragrant, redolent with the odors of grape or waterlily. Select a few, too, among the

whites, or plicatas, that are cream, or white delicately penciled with mauve and violet, for their airy grace when you brave the dew on a moonlight night. And lastly put the rich, sombre purple and maroon varieties and others with colors that do not carry well into the garden where they will add character as accents. All these points and many more will add immeasurably to your pleasure as you become intimately acquainted with the charm of each individual iris.

The early *Pumila* hybrids make excellent informal borders next the path, and and in drifts now running to the back, or reaching to the front, can be arranged the majority of the varieties that range from 15-36 inches in height; while behind and in selected spots can come the five foot stalks. These giants are mostly of recent* introduction and I call them of the garden "decorative type" as they seem best suited to

planting in clumps that will reveal the branching habit and the poise of the immense flowers. In England they are often staked as a precaution against wind and rain.

The effect of light and shade on the different iris colors, or on even the same tone in different varieties, is a study in itself. In some the beauty is intensified by the flickering shadows from nearby trees; others reveal a vivid vitality in the sun of noonday which they lose when brought indoors; while an ethereal beauty envelopes my planting of *Pallida Dalmatica* "Princess Beatrice" when the level rays of the setting sun make translucent the flaring falls. And to an even greater degree are iris colors modified by artificial lighting. For cutting, use the pale colors, whites and near-whites tinted with blue, lavender or pink, mere touches of color that suggest combinations with darker tones. Do not neglect the decorative value of the foliage either within or out-of-doors. An iris leaf seems one of Nature's bequests that cannot be bettered by man or art as an accompaniment to the iris flower; the contrast of the strength and simplicity of its upright, sword-shaped blade with the delicate tissue of rounded segments grouped in threes, the subdued

Barclane, a "decorative type" of Iris.

*For further information write R. S. Sturtevant, Sec'y, Wellesley Farms, Mass.

frosted green with brilliant colors delicately lined in character with the whole bloom, form perfect counterparts.

For color in masses I should choose from a list containing *Florentina alba*, Ingeborg, Mrs. Horace Darwin, and Fairy; for white or pearl—Mrs. G. Reuthe, Glori de Hillegom, *Pallida Dalmatica*, *Juniata*, and Parc de Neuilly in increasing depth from white to violet; *Flavascens* and *Aurea*, yellow selfs; Mrs. Alan Gray, Her Majesty, and Wyomissing for delicate pinks; Caprice for claret, and Loreley, Mithras, or Princess Victoria Luise, and the Blue and white Rhein Nixe for bicolors.

For the garden beds I will tell you what I consider superfine, but I want you to remember that there are hundreds of good ones, much less expensive ones in fact, but as we become more critical our appreciation of the following novelties grows: Ma Mie, Parisiana, Milky Way, Damozel, Cygnet, Mme. Chobaut, Delight; White

Knight, Myth Avalon, Mlle. Schwartz, Queen Caterina, Balboa, Halo, Neptune, Mme. Cheri, Moa, Opera, De Guesclin, B. Y. Morrison, Prince Lohengrin, Reverie, Dominion, Tyrian, Wild Rose, Crusader, Rose Madder, Mme. de Gaudichau, Shekinah, Prospero, Asia, and Ambassadeur. All these are of the best, among their varied colors each should be able to select his or her ideal.

Somehow we never think of the iris as a florist's flower and yet last year some of the finest window displays in San Francisco were of irises, bearded irises. My correspondent writes that the light tones were in fine demand and that, if cut in bud and delivered by hand the results were extremely good. Let us hope that in time the iris will become as familiar to the city dweller as it now is to all who have a bit of garden. Given plenty of sun and good drainage they will thrive for the most careless of growers. Their beauty is within the reach of all.

Cultural Suggestions for the Gladiolus

A. E. KUNDERD

WHILE the *Gladiolus* gives satisfaction with ordinary care and culture in average soils, the superior blooms which are produced by special attention more than justify the extra care.

If possible, each season a new location, or a new soil at least, should be used so that bulbs are not planted more than every third year in the same soil. As far better results are obtained from rich soil, it is advisable to spade in a good covering of manure late in the Fall preceding the plantings, and in Spring to spade deep and to pulverize thoroughly as soon as the soil is in proper condition.

To have a long blooming season one should plant at intervals of about two weeks from the time when the garden is started until the middle or latter part of June. Bulbs can be planted four inches deep and over in mellow soils, and from four to eight inches apart in the row; deep planting prevents, to some degree, the plants from falling over in their blooming period. The blooms will have greater resistance against the sun and more lasting qualities if the soil in the beds are frequently and thoroughly watered at evening. Do not allow a soil crust to form in rows among the plants, but cultivate well, especially early in the forenoon following a watering the previous evening. When the blooming spikes begin to appear, cultivation should only be about two inches deep. Once every week or ten days liquid fertilizer or prepared sheep manure can be applied to the soil near the rows, but one must be careful in not making the application too strong.

To intensify deep shades, apply Scotch soot when the plants are about half grown; and it is said that the delicate shades can be clarified by applying weak lime water just before the blooms begin to open. Nitrate of soda, about a tablespoonful to two gallons of water for each dozen plants, is very beneficial and may be applied to the soil once every week or ten days after the buds show color. If one prefers the pulverized nitrate of soda, this may be sprinkled over the soil, raked in and watered.

Slender stakes of wood or bamboo, painted light green to make them less conspicuous, serve as fine supports to the spikes during their blooming season. Where horizontal lines are used, fasten them to the end posts firmly set and stretch the wires tightly. A

few more stakes should also be placed at intervals along the lines. Instead of using cord to tie the spikes to the supports, tie them carefully with strips of cloth.

When the first flowers open, one should cut the spikes, and allow them to bloom in the house in order to secure the best results. Every morning the stems should be cut a little with a long slope and not squarely across; rinsed and given fresh water, and the wilted blossoms removed. The blooms are refreshed and improved by being placed in a cool cellar during the night.

If good bulbs are desired for the following year, four to five strong leaves should be left on the plants when cutting the spikes.

In the Fall, dig the bulbs before the plants are too ripe, and cut off the tops. Dry well in the air and sunshine, cure thoroughly indoors for a few weeks, then store in a cool, dry cellar. A covering of sand while in storage (after bulbs are well cured) is a protection against frost or dampness, which tends to develop disease. Keep as near 40 degrees as possible.

Should bulbs become affected with disease or scab, they may be benefited by one of the three following remedies: Soak bulbs in a bichloride of mercury (corrosive sublimate) solution of fifteen grains to each gallon of water for twenty minutes. Or: Use two ounces of corrosive sublimate dissolved in fifteen gallons of water and soak for two hours (for smaller amounts in proportion). Or: Use one ounce of 40 per cent formaldehyde to each four gallons of water and immerse bulbs for twenty minutes to one hour. I have left bulbs immersed for longer periods in even stronger solutions, but care must be exercised not to make the treatment too severe for fear of injury. Sometimes it is best to remove the peel before bulbs are treated. These treatments are generally employed just before planting.

The Tropical Rain Forest

WILLARD N. CLUTE

BACK and forth across the equator moves the sun on its annual journey from the tropic of Cancer to the Tropic of Capricorn, carrying with it a belt of rainfall that makes the so-called Torrid Zone perennially green. There are, to be sure, many places in the tropics where desert conditions prevail; in fact, most of the great deserts of the world lie fairly close to the equator, but such regions are always caused by unusual conditions such as a mountain range intercepting the moisture-bearing winds. In other parts of the tropics the moisture is not only abundant, it is superabundant. Just how abundant it is may be realized when it is known that if all the water that falls on the Eastern United States were collected for a year, it would not equal the amount that has fallen in a single day in the tropics! In some unusually wet spots there is more than six hundred inches of rainfall a year—more than fifty feet! Under such conditions rivers rise with great rapidity, sometimes thirty feet in an hour. A body of water that behaves in this way may give peculiar ideas to the natives. In Jamaica they often speak of the river as a separate entity. They say it is "down" when it is running bank full and "up" when it is in the clouds overhead and preparing to come "down."

The effect upon vegetation of this enormous rainfall, coupled with the maximum heat and light can scarcely be imagined by one who has not seen the tropical rain forest. So luxuriantly do all sorts of vegetation grow that one must literally chop his way through it if he leaves the beaten track. Everywhere the forest is a dim, shaggy, dripping, wilderness of plants.

One of the first differences to be noted between the rain forest and the forests of temperate regions is the way in which each species is scattered through the woodlands. There is seldom a grouping of single species to form colonies such as we find in our forests of oak, pine, beech, maple, and the like. The number of different species is, of course, infinitely greater and they usually attain a larger size. A new form of trees is also noticed—a columnar form with unbranched stem, and ample leaves springing from a single bud at the summit. Of this type are the various palms, tree-ferns, dracænas and numerous others. The excurrent type, represented by our pines and spruces, with a central stem from which smaller branches are regularly given off is usually rare. Most of the forest trees, however, are of the solvent type, such as is found in our elms and oaks and at a little distance the tropical forest could not be distinguished from a temperate region forest unless it happened to have an unusual number of palms in it.

In the desert the most interesting forms of plants have been evolved by adaptations for securing and conserving the scanty supply of moisture, but in the rain forest may be found many devices for avoiding excess moisture. Often the leaves have long slender tips for throwing off the water away from the roots. With an abundant and perennial supply of water and unvarying warmth, a new phase is given to the struggle for existence. Competition is now for sufficient light. On the forest floor are great numbers of mosses, ferns, and creepers which have learned to exist in the semi-twilight cast by the tall trees—shade plants, we call them—but plants which need more light have moved to the branches of the forest canopy. Thousands may be found on a single tree. Among the plants with this epiphytic habit one notes a large number of orchids, bromeliads, ferns, club-mosses

and the like. Great lianas, or woody vines, often with stems as large as a middle-sized tree, loop from tree to tree and bind the vegetation into a solid mat of verdure.

Where the forest is more open, for any cause, giant herbs appear. Some of these are so large as to pass for trees as in the case of the banana. This plant, however, as can easily be seen in the usual greenhouse, is really an herb equivalent to the iris, day-lily or peony of more boreal regions. Other great herbs are the ginger, arrow-root, canna, taro, and many ferns.

After botanizing in the tropical rain forest for a time the student discovers that many of the plant families which are characteristically herbaceous in regions nearer the poles are here prevailing woody. This is especially true of the *Leguminosæ* or pea family nearly all of whose species are woody in the tropics. It is scarcely a surprise, therefore, to learn that there are morning-glory trees and that violets frequently grow on bushes. The verbenas, the composites and even the grasses are represented in the tropics by species of truly tree-like proportions. As a matter of fact, only about a dozen species out of a hundred in the tropics are not woody. This, however, is to be expected. In a region where every requirement for plant growth is abundant, the vegetation naturally reaches its maximum.

The tropical rain forest may be described as evergreen, but it is not evergreen in the sense that the leaves never fall. Usually the old leaves drop one at a time all through the year as new ones are developed. There are some species, however, even here, that take, as it were, an annual vacation, throwing off their leaves and standing bare for a time, even during the height of the season. Most curious of all is the behavior of the tropical almond whose branches have not learned the advantage of effective teamwork and which rest, therefore, as the whim seems to strike them. Such a tree presents a remarkable appearance with some branches in full leaf and others in complete rest.

The visitor to the tropics, recalling the beautiful flowers he has seen in our conservatories, expects an unusual floral display but in this he is commonly disappointed. There are, to be sure, occasional outbursts of bloom that fairly dazzle the eye, as when the logwood is in blossom or the flame tree hangs out its flowers, but seldom does the tropics have anything to offer more beautiful than our northern woodlands in May. Though many flowers are found in the torrid zone, they are lost and their beauty eclipsed by the all-pervading leafiness. Another result of the mild climate is the absence of a thick bark on the trees. The stems of even large specimens are often a decided green. There is nothing to prevent flowers springing from the trunk and larger branches and many plants bear flowers in this way. The chocolate plant is noted for producing its fruits from wood many years old. In our own region practically the only woody plant with this habit is the red-bud. With us, owing to the progress of the seasons, each species of plant has its regular time of bloom. Violets and roses bloom at one end of the growing season and golden-rods, asters and gentians at the other, but in the rain forests the plants are at no necessity of conforming to a given temperature or time of year and therefore bloom whenever impelled to do so. Many are in almost continuous bloom with perhaps a maximum when the rainy season is at its height.

The Progress of the Rose in America

EDWARD A. WHITE

Professor of Floriculture, Cornell University

"The interest in the rose cannot pass. The appeal of the flower is practically universal. The variety in form and color is wide and the adaptation remarkable. It has become part of the experience of the race."—L. H. Bailey in "The American Rose Annual," 1917.

PROBABLY no other genus of ornamental plants appeals to so great a number of people as does the rose. This is due in a large measure to the varied characters of the many species and varieties, also to their wide range of adaptation to different soils and climates.

It would indeed be interesting if there were available, photographs of ancient American rose gardens, or of roses growing in greenhouses during earlier periods of the

were as nearly ideal as it was possible to have them. It has been within a comparatively few years that American rose breeders have been working to produce ideal species for the landscape, the garden and the greenhouse. To see the splendid results of recent achievements in rose breeding, it is necessary to visit our best public parks, to make the June pilgrimages with the members of The American Rose Society to their test gardens, to visit the gardens of American rose enthusiasts, or to attend some of the large exhibitions of cut-roses, such as the National Flower Show in Indianapolis, Indiana, the Winter exhibition of carnations and roses at Hartford, Conn., or the New York Flower Show. In places such as these the best American roses may be seen.

Van Fleet Hybrid of Rosa Wichuraiana X R. Pernetiana. (Courtesy of American Rose Society.)

commercial cutflower industry, so that comparisons might be made between the earlier methods of culture and those of today. Within the memory of the writer the commercial growing of cut-roses has developed from comparatively small ranges with a limited output, to huge "rose factories" where the daily output numbers thousands of blooms. When one sees the huge shipments of roses from some of the large rose production centers one wonders where they all go. However, the American people demand them all to beautify their homes, to cheer the sick, to carry expressions of sympathy to the afflicted, to make more joyous the marriage ceremony; in short, to brighten and make glad every occasion and to enable the American people to "Say it with Flowers."

The history of the development of both garden and greenhouse roses in America is interesting. During the early years of rose growing little attention was paid to breeding varieties suited for our peculiar conditions. We took what the Europeans sent us and supposed they

The native species have not played a large part in the development of better American types. A few, however, are suited for ornamental landscape effects. Among them are *Rosa setigera*, *R. blanda*, *R. carolina*, *R. lucida* and *R. nitida*. *Canina* and *rubiginosa* are European species which have escaped from cultivation. It has been the species from Europe and Asia that have so largely influenced the present day type of ornamental roses.

Those who had an opportunity to visit the late Dr. Van Fleet, at Bell, Md., and to see there his results with hybrids of *Rosa Willmottiae*, *R. Hugonis*, *R. altaica*, *R. rugosa*, *R. omiensis*, and *R. Moyesii*, realize how seriously rose progress in America has been retarded by the "passing on" of a wonderful rosarian. His article in "The American Rose Annual" for 1921 on "Rose-Breeding in 1920 at Bell Experiment Plot" should be read by every lover of the rose. Speaking of the favorable climatic influence for rose pollination during the season of 1920, Dr. Van Fleet wrote, "The harvest in matured

seed was greater than heretofore and covered the widest range of species yet attempted, the special features borne in mind being, hardiness, disease resistance and good

can gardens." "Particular attention was given in 1920 to the utilization of the lesser-known northern species of both hemispheres such as *Rosa inodora*, *R. pulvuru-*

Hybrid of Rosa Hugonis X R. altaica, two years old (Courtesy of American Rose Society.)

garden appearance of plants. Elegance, profusion and continuity of bloom, are of the highest importance and every effort is made to develop these perfections in hybrid progeny. There are already too many weak

lenta, *R. Murielæ*, *R. hibernica*, *R. micrantha*, *R. involuta*, and *R. Jundzillii* of the Old World and native *R. Macounii* and *R. nutkana*, and the most northern forms of *R. nitida*, *R. pratincola* and *R. lucida* or *R. virginiana*.

Rosa Willmottiae in bloom at Bell Experiment Plot. (Courtesy of American Rose Society.)

varieties that produce a few exquisite blooms under exceptional conditions of culture but new varieties that do not require incessant coddling are needed for Ameri-

There is considerable diversity in garden adaptability among these extremely hardy wild roses and crossings with the several attractive new Chinese species, and with

highly developed florists' varieties may open up new features of value in the offspring. Seeds of most of the northern species are of slow germination and probably several seasons will be needed to bring out their possibilities."

Rosa multiflora has been the parent of many climbing varieties which have left an indelible impression on the mind of rose lovers. The more trailing or prostrate, evergreen species *Wichuraiana* has played an important part in the development of the so-called "Pillar Roses." Such men as Jackson Dawson, Dr. Van Fleet, M. H. Walsh, W. A. Manda, Hoopes Bros. and Thomas and others, saw the possibilities for improvement in the desirable characters of each, through hybridization, and crosses were made between these two species; also between these and *R. setigera* and the Hybrid Teas and Hybrid Perpetuals. Among the best of the present day varieties which have resulted from such crosses are Dawson (*R. multiflora* × General Jacqueminot, H. P.), Farquahar (*R. Wichuraiana* × Crimson Rambler, H. M.), Dr. Van Fleet (*R. Wichuraiana* × Mme. Gabriel Luizet, H. P.); *Gardenia* (*R. Wichuraiana* × Perle des Jardins, H. T.), American Pillar (*R. Wichuraiana* × *R. setigera*); and *Christine Wright* (an unnamed *Wichuraiana* seedling × Caroline Testout, H. T.).

Rosa multiflora crossed with Teas and Hybrid Teas has also given a type of the so-called "Polyantha Pompons" like George Elgar and Cecile Brunner, varieties now so popular. There have also been produced from similar crosses the dwarf polyanthas so useful as bedding roses. Varieties of these like *Echo*, *Triomphe Orleansais*, *Maman Turbat*, and *Mme. Jules Gouchault* are also much used by florists in forcing for Spring bloom.

The Tea Roses became popular in America during the middle of the nineteenth century. *Rosa odorata*, or the original Tea Rose with double blush flowers, was introduced into England from Western China in 1810, and in 1824 a form with pale yellow flowers was introduced. From the crossing of this species with *Rosa chinensis*, the Bengal Rose, and other Chinese species, the present day Tea Roses have been produced. Among the older varieties of Tea Roses still grown to a considerable extent for commercial purposes, particularly for corsage bouquets in retail stores is Bon Silene. This was originated by Hardy in 1835 and is one of the few varieties which has stood the long-time test. Catherine Mermet originated by Pierre Guillot in 1869 was the parent through bud variation, in 1885, of the Bride. This was the principal white variety grown in greenhouses until the advent of the Hybrid Tea, White Killarney, in 1909. Bridesmaid, the pink Tea Rose popular as a greenhouse variety, was also produced by a bud variation on Catherine Mermet in 1892.

The species of roses which have been chiefly responsible for increasing the vigor of garden varieties are *Rosa gallica*, the Provence Rose, *R. borbonica*, the Bourbon Rose, and *R. damascena*, the Damask Rose, Hybrids of these species with *R. chinensis* and *R. odorata* have given the present day type known as Hybrid Perpetuals or Remontants. This race became popular from 1860 to 1890. Many Hybrid Perpetuals are now grown, but their more limited blooming period makes them less in demand than are the more constant blooming but less hardy varieties of Hybrid Teas. Frau Karl Druschki, General Jacqueminot, Paul Neyron, and Hugh Dickson are still found in the majority of American Rose gardens.

Near the middle of the nineteenth century European rose breeders began to search for some method of increasing the hardiness of Tea Roses. As a result existing varieties were crossed with Hybrid Perpetuals. One of

the first results of such a cross was achieved by Pierre Guillot of Lyons, France, when he originated La France.

This was, however, not recognized as a new type until 1890. The first product of the hardier type which was classified as a Hybrid Tea rose is said to have been Cheshunt Hybrid, introduced by George Paul in 1873. The writer had the pleasure of a day with George Paul shortly before his death last September. Mr. Paul then showed him with great pride, two of his most recent hybrids, "Paul's Perpetual-flowering Lemon Pillar" and "The Premier," a hybrid of *Rosa lutescens*.

Hybrid Tea roses of European origin have played an important part in American rose breeding. They have furnished the parents for many of our best varieties. Honor must be given Alex. Dickson for Killarney, William Paul for Ophelia, Pernet-Ducher for Mrs. Aaron Ward, Sunburst, Souvenir du Claudius Pernet, and to many others for varieties which have been and are to be such important factors in American rose production. However, our American breeders have been doing most excellent work and no finer results have been achieved anywhere than those of American rosarians.

John Cook, Baltimore, Md., has given us the following which have been foremost among commercial varieties: My Maryland, 1908; Radiance, 1908; Francis Scott Key, 1913; Mrs. John Cook, 1919; Glorified La France, 1919. E. G. Hill, Richmond, Indiana: Richmond, 1905; Rhea, Reid, 1908; Columbia, 1916; Premier, 1918; Mme. Butterfly, 1918; Hill's America, 1921. Alexander Montgomery, Hadley, Mass.: Wellesley, 1905; Crimson Queen, 1912; Mrs. Chas. Russell, 1912; Hadley, 1914; Crusader, 1919; Pilgrim, 1919. Frederick Dorner & Sons Co., Lafayette, Indiana: Hoosier Beauty, 1915. In distinctly garden varieties of Hybrid Teas, Captain George C. Thomas has recently produced Bloomfield Abundance and Bloomfield Progress, 1920; Howard and Smith; Los Angeles, 1916, and Miss Lolita Armour, 1920. These are but a few of the recent valuable acquisitions to American varieties by American rose breeders.

The field of rose breeding is a broad one and it is safe to say that the work our Americans have thus far done is but a beginning; the future holds much of promise.

Other agencies are at work in America which stand pre-eminently for rose progress. "The American Rose Society" is carrying the rose far to the front as a flower for all classes of people. The work of the organization is governed by a body of men who are generously donating their money, time and thought to those subjects which stand for progress in every phase of rose growing in America. The test-gardens in various sections of the United States which are under the direction of the A. R. S. have been valuable agents in demonstrating the adaptation of various species and varieties to different soils and climates. The American Rose Annual, which the organization publishes for its members, is full of valuable rose literature. The volumes constitute a rose library and no one interested in any phase of garden work can afford to be without them.

With the increasing interest shown by our American people in rose growing, with the literature which is accumulating year by year, and best of all with the introduction of the hardier varieties, which are eliminating the discouraging element of Winter killing in the northern section, rose progress in the United States is certain.

There are two things necessary for the enrichment of life, mentally, physically, socially, and spiritually. They are very simple and are known to all men. One is hard work and the other is a determination to do right. —Calvin Coolidge.

Late Rose Introductions

SOUVENIR de Claudius Pernet, a *Pernetiana* seedling, is a rose that has been long waited for. It is a golden yellow rose which will stand our vigorous requirements and will not turn white around the edges as does most every yellow rose. The orange yellow shade so prominent in such sorts as Mrs. Ward or Sunburst is entirely absent here, and Souvenir de Claudius Pernet with its clear shining yellow color has created a veritable sensation among all visitors to the numerous exhibitions where it has been shown.

Max Graf has attractive, single, bright pink flowers, with petals even more crimped than the pink form of *Rugosa*. While an excellent climber, or pillar rose, it is even more appealing as a ground cover, surpassing, in this respect, any of the *Wichuraiana* varieties. It is especially attractive

when planted on a steep bank, or trailing over a stone wall.

Mrs. William C. Egan, a new hybrid tea rose, is named in honor of the wife of William C. Egan, well known and appreciated for his love of horticulture. It is an extremely vigorous, healthy grower, and popular for individual plantings in small gardens as well as for massed effect in large gardens. The reverse of the petals is of a pleasing shade of light pink, the interior a deep flesh color with a golden line at base of petals. Its long pointed buds are of perfect form, developing into flowers of good shape.

Potash-Marl

E. N. CLEVELAND

POTASH-MARL is a natural fertilizer and as its name indicates is a marl containing a high percentage of potash, as distinguished from Calcareous or Lime-Marl.

The use of marl was fully understood at the beginning of the century. Since the time of the Roman conquest, and probably before, the marl beds of northern France and southern Belgium have been constantly exploited. Great hollows are found in many of the fields of northern France made by the excavation of marl many centuries ago. The true function of marl, however, was but little understood, and even its chemical composition was practically unknown by those using it.

Potash-Marl is a consolidated mass of sandy particles of emerald green color composed of potash, iron and phosphoric acid minerals, together with the decomposed and crystallized remains of whales, sharks' teeth, mollusks, fishes and other nitrogenous materials.

The following is an extract from a scientific report made by Dr. Hal Trueman Beans, Ph. D., of Columbia University, New York:

"Glaucouite, the principal mineral constituent of greensand, is essentially a hydrated silicate of iron and potassium, associated with minerals containing aluminum, calcium, magnesium and phosphorus. Owing to the fact that it is a hydrated silicate, it is easily decomposed by the most varied chemical reagents, including even weak organic acids. Silicates of this class are to be sharply distinguished from non-hydrated silicates such as the feldspars, which are extremely difficult to decompose. Furthermore, hydrated silicates absorb additional water in large quantity and are, therefore, further distinguished from the feldspars and similar silicates which show no tendency to retain water.

"The analysis of Potash-Marl gave this result:

Moisture	4.05%
Loss on Ignition	4.83
Iron & Aluminum oxides.....	28.52
Insoluble Matter	50.79
Phosphorus (P_2O_5)	1.14
Calcium Oxide (CaO).....	2.14
Potash (K_2O)	6.50

"In order to determine the relation between the potash and phosphorus in the available form as determined above, and the total potash and phosphorus contained in the greensand, separate determinations of the total quantities were made, with the following result:

Total Phosphorus (P_2O_5).....	1.84%
Total Potash (K_2O).....	7.24

"It thus appears that approximately 90 per cent of the total potash is in a form which will ultimately be available to plant assimilation. It appears therefore from the above analysis and from the well-known chemical characteristics of glaucouite, that these samples of greensand contain in a reasonably readily available condition all of those inorganic mineral substances which are essential to plant growth. While it is true that practically none of this material is in a water-soluble condition, nevertheless, glaucouite is so easily decomposed that the above figures may properly be taken to represent that portion of the material which will actually become available to the plant."

Potash-Marl is both a direct and indirect fertilizer, as it improves both the chemical and physical properties of the soil. It acts in conjunction with the elements at all times to assist in unlocking plant food from the nat-

ural soil as well as from the life elements contained in itself; correcting acidity and prompting nitrification.

The New Jersey State Geologist's last report, ending June 30, 1920, just published, makes the following statement as to the solubility of Potash in greensand: "In spite of its low solubility, recent experiments show that plants in their early growing stage will assimilate potash from greensands as effectively as from the usual soluble commercial potassium salts."

The phosphoric acid contained in the Potash-Marl is acted upon the same as the potash, it becomes slowly soluble through chemical action and weathering. The iron and aluminum oxides in Marl produced quantities of nitrogen, although in the analysis of the Marl no credit is given for it producing any nitrogen which is of great value as a fertilizer. Quoting from "Agricultural Chemistry," by Justus Liebig, Ph. D., F. R. S., one of the greatest chemists in the world, Page 103, "The oxides of iron and aluminum are distinguished from all other metallic oxides by their power of forming solid compounds with ammonia. Minerals containing oxide of iron also possess in an eminent degree that remarkable property of attracting ammonia from the atmosphere and retaining it."

Dr. Edmund Ruffin, of Virginia, began his experiments with marl in February, 1818. From land thus treated he obtained an increase of 40 per cent over the crop on similar land untreated. Encouraged by this result, he planned more extensive experiments for future years. Without entering into the details of these trials, the result may be stated as overwhelmingly in favor of the use of marled fields. The yield was more than twice as great as from the same fields before marling.

The experiments were continued for a long series of years, accurate records being kept of the history of each plot of ground, frequent comparisons being made between the measured yields of marled and unmarled fields. Marl was tried with and without manure and manure was tried with and without marl.

The greater the number of experiments and the more numerous the results obtained the greater proof was given that the use of marl was of great advantage.

The careful manner in which the experiments were carried on show him to rank as one of the most intelligent experimenters of his time. He searched the literature of every age for mention of the occurrence of marl and the history of its publication to the purpose of agriculture. He was familiar with foreign publications on the subject.

United States Government Report, Published in 1910, Page 761 states: "New Jersey Marl has been of incalculable value to the region in which it is found. It has raised this region from the lowest stage of agricultural exhaustion to a high state of improvement.

"Lands which in the old style of cultivation had to lie fallow, by the use of marl produce heavy crops of clover and grow rich while resting. Lands which had been worn out and left in common are now by the use of this fertilizer yielding large crops of the finest quality. Everywhere in the marl district may be seen farms which in former years would not support a family, but which are now making their owners rich through productiveness.

Extract from "The Grapes of New York," by Prof. U. P. Hedrick. Subject: Grapes Suffering from 'Yellow'
(Continued on page 91)

The Dahlia

THOMAS PROCTOR

THE Dahlia, now prominently identified as one of our most beautiful Autumn flowering plants, has rapidly advanced in popular favor during the last few years. No doubt, the many new and gorgeous varieties introduced by the hybridizers have in no small measure contributed greatly to the popularity of this plant.

There is now a vast contrast between the flowers of the Dahlia we have today, from what they were twenty or thirty years ago when we had but a few indifferent varieties to adorn our homes with. Now we have hundreds of rare and beautiful varieties to choose from, represented by all the colors of the rainbow.

CULTIVATION

The cultivation of the Dahlia is by no means difficult, providing their wants are carefully attended to during the growing season. One should bear in mind, for instance, that the Dahlia is a moisture-loving subject, and therefore, should never be allowed to suffer for the want of water at any stage of its growth.

While we all know that this plant will grow and produce flowers in almost any kind of soil and situation, one who is ambitious to win the silver cup with his blooms will endeavor to select the most promising location he can find in order to make a success of his efforts.

I have found that a level sunny position facing south, and well protected from stormy winds, gives the best results. If the grower has time at his disposal to trench the ground for the reception of his plants the results will be all the better for the extra labor involved. If that is not feasible, digging or plowing will suffice; in either case, however, the ground should be incorporated with well rotted cow manure with a small sprinkling of bone meal included.

STAKING AND PLANTING

When the preparation of the ground is accomplished, strong stakes should be provided and firmly placed in position, four feet apart each way, and near the top of each stake a six inch label tacked on for the name of the variety to be planted. Around the bottom of the stakes a little pulverized sheep manure forked in is of much benefit in giving the young plants a start.

It makes little difference whether tubers or rooted cuttings are used for planting. The varieties that are intended for the production of exhibition blooms should in no case be planted too early. June 5 to 10, or even a little later will be quite soon enough for the latitude of Long Island. If set out much in advance of the dates mentioned, the plants will become exhausted, and consequently will not produce exhibition blooms. When the plants are six inches in height, the points are pinched out in order to induce the plant to send up more growths. As soon as conditions will permit, the young shoots should be carefully tied to the stakes as they extend in length. With varieties that are intended for the production of exhibition blooms, one bud only should be left on each shoot to develop; otherwise, several buds may be left on, as desired by the cultivator.

FEEDING

The Dahlia, like the Chrysanthemum, responds well to generous treatment, and there is nothing better in my opinion, than liquid cow and sheep manure for that purpose, applied alternately twice or three times a week according to conditions. Scotch soot also in liquid form and used once a week when the buds are well advanced, plays a very important part in the development and color

of the blooms, as well as the foliage. Nitrate of soda is also considered beneficial if used with discretion.

Feeding should commence when the plants have become well established, lightly at first, then gradually increasing the strength until the maximum is reached, that is, when the buds are well advanced. When the latter begin to show color, feed lightly again until the blooms are three-quarters developed; then stop using the cow and sheep manure, and finish off the blooms with a weak solution of the Scotch soot.

INSECTS

Insects are troublesome in most sections of the country and will do considerable damage to the foliage if not checked in time. I find that Ivory soap, dissolved in water and applied to the foliage with a spray pump once a week will invariably prevent the ravages of all kinds of insects and keep the foliage in healthy condition.

WINTER STORAGE

As the Dahlia is a very tender subject, the first good frost generally ends its usefulness as a cut flower producer. When that takes place, the stems should be cut back to within eight or ten inches from the ground; the labels with the names of the varieties taken from the stakes and securely fastened to the stem that remains. If the weather is dry and conditions otherwise favorable, the plants should be lifted—the dirt partly shaken off—and transferred to a frost-proof cellar, where the light is partially excluded, and be left there for the Winter. Care must be taken to see that the tubers do not shrivel, generally the result of a too hot and dry atmosphere. If that condition should occur, sand or dirt, scattered over the tubers, will in most cases remedy it.

To get the best result from the plants it is essential that the ground be constantly cultivated, not only to keep down the weeds, but also to retain the moisture. This should be particularly attended to when the weather is dry and hot. Never allow the plants to wilt for want of water or the result will be disastrous if exhibition blooms are looked for. Be prepared at all times for the sudden approach of destructive wind storms, or the plants may be ruined, if not protected and carefully tied to the stakes. Remove all weak and useless growths; also flower buds that are in excess of those required for development. The fewer the buds left, the better will be the blooms. Keep a sharp lookout for insects, and before they commence their depredations, apply the remedy as advised for prevention. Study carefully the plant's requirements at every stage of its career, and success should be the reward.

Competent Gardeners

The comforts and products of a country home are increased by employing a competent gardener; if you want to engage one, write us.

Please give particulars regarding place and say whether married or single man is wanted. We have been supplying them for years to the best people everywhere. No fee asked.

Seedsman and Florists

35 and 37 Cortlandt St., NEW YORK CITY

Roses and the Rose Garden

ARTHUR SMITH

WE have previously alluded to separate gardens devoted to special purposes, as being possibilities in connection with home surroundings, and certainly where there is room a good Rose Garden is one of the most desirable features.

The genus *Rosa* is a very large one, and perhaps in no other is there so much dispute among botanists regarding the number of species contained in it. While a French botanist has listed and described some four thousand as being distinct species, the majority of botanists confine the number to about one hundred. While some knowledge of roses from a botanical standpoint is interesting in connection with the parentage of the rose of today as known in our gardens, from a purely horticultural point of view botanical classification is of minor importance as, with one or two exceptions to be noted later, all cultivated roses are hybrids, although the leading garden-groups follow to some extent specific lines. At the same time it is impossible to trace back all of the hybrids to their original species with accuracy.

We know that from the earliest times when any attempt at gardening was made at all, great dependence was laid upon the rose. We have a race of roses which have come down from the ancient gardens of Persia; the medieval gardens have given us others, and down to the present time gardeners have always vied with each other to produce new and wonderful varieties of this classic plant which has been known for ages as the Queen of Flowers. Consequently we have now a rose for every situation and, where the climate is genial enough, roses in bloom every month of the year. The results of domesticating the rose are marvellous, yet, so far as being at the end of possibilities in the way of producing kinds more suitable for the extremes of climates found in this country are concerned, the real breeding of roses has little more than begun and a rich field for the future is indicated. In this direction the passing away of Dr. Van Fleet is a tremendous loss to horticulture as the success of his work as far as the time allotted to him permitted, proved that he was working along the right lines.

Leaving out botanical considerations entirely, horticultural roses may be divided into three groups: "garden" roses, a term confined to tea roses, hybrid teas and hybrid

perpetuals or remontant; climbing roses; and shrubby roses.

Those contained in the first group are the result of hybridizing about a dozen species, and selections and seedlings from the resulting hybrids. These roses do not lend themselves to landscape effects because they have comparatively little foliage and lack strong shrubby characteristics. These highly improved roses are essentially flower-garden subjects—hence the term given them. To produce anything like good results from them they must be grown by themselves so that they can receive the special care in the way of soil treatment, pruning, watering, feeding, which could not be conveniently given elsewhere.

A Rose Garden. (Courtesy of Bobbink & Atkins.)

It is worth while to state some of the distinctions between the three classes of which this group is composed.

The tea roses are admired the world over for their delicious fragrance, the exquisite form and rich tints of their flowers and value for cutting. They are the least hardy of the group and require special methods for protecting them in climates of severe Winters.

A good way, where they cannot be wintered in the open, is to place cold frames over them, the size of bed and position of the plants being previously arranged with this idea in view. The slope of the frame should be to the east. It is important to remove the sash when the temperature is at thirty degrees or above, and air should be given when the thermometer is at twenty.

The hybrid tea varieties have some of the characters of the teas, especially their constant blooming qualities, and most of them have some of the hardiness of the hybrid perpetuals, but they require to be well protected during Winter with strawy manure or leaves in climates where the temperature reaches zero. This class has been produced by crossing the teas with hybrid perpetuals, but there is considerable variation among them, especially as to hardiness, as well as in flower production, and the most satisfactory are those partaking of the good qualities of both.

The hybrid perpetuals are hardier than the preceding, and more vigorous and robust in habit, their flowers being larger, some of them of immense size and generally of more substance than either of the others. They

flower as a rule only early in the Summer, but as an offset we are rewarded at that time with a greater abundance of larger and longer keeping blossoms. Many varieties, not only produce a wealth of flowers during June and part of July, but do so at intervals all the season with an increase towards the Autumn. This is especially the case if, after the first blooms are over, the bushes are cut back to encourage new growth of wood, for, with these, as with almost all others, it is only upon new wood that flowers are produced.

A rose garden is practically only a garden for the production of roses of the highest quality in the greatest quantity, in the same way as a vegetable garden is for the production of vegetables, therefore everything should be subservient to these ends.

For convenience as much as for anything else a rose garden should be rectangular in shape and its beds laid out along formal lines. Fancy beds of intricate patterns are not only entirely out of place but at the same time create considerable inconvenience and cause waste of room. In addition to the fact that these roses are not themselves any addition to the appearance of a landscape, the formalness of a garden of this kind renders it objectionable as a part of a harmonious natural planting, therefore some means must be taken to prevent it producing a discordant note in home surroundings.

A rose garden or rose border should be in an open spot away from high buildings and tall trees so that the plants can obtain plenty of sun and air, and the ground may have a little slope in any direction, but all other conditions being equal, a gentle slope to the southeast is preferable.

Having chosen the situation and decided upon the extent of ground to be devoted to this purpose, some method of planting the surroundings must be devised so as to avoid making the rose beds part of the landscape. I have known rose gardens to be merely surrounded by a closely clipped privet hedge, which neither from a landscape point of view nor from any other, does anything to relieve the situation; in fact it would be better to have a rose garden entirely exposed and part of the landscape than to surround it by a formal unsightly hedge. It is better to screen a rose garden and any other special garden by some natural planting arranged so as to harmonize with the general landscape plan, so that, as far as one can know from looking towards it, it might be the boundary planting of a lawn with nothing but the street on the other side. It is important that the connection between the screen of the special garden and the other planting be invisible and that the entrance or entrances be arranged with this idea in mind. It is of course impossible to make hard and fast rules regarding whether this garden should be screened all round or not, generally speaking one side at least may be open without bad effect. At all events, considering the rose garden from the inside—whatever may be planted around it—a space all along the inside of the boundary should be left to the width of about eight feet, which can be devoted to a border of five feet and a walk of three feet. It is very effective to have this border devoted to the roses comprised in the shrubbery group combined with herbaceous perennials. The rest of the area can be divided into beds three feet wide leaving two main walks three feet in width at right angles across the center, with such subsidiary walks two feet wide as may be necessary to the area. These walks are for the purpose of enabling everything connected with the culture and care of the roses to be done without stepping off a walk.

While thorough preparation of the soil is important for all plants it is especially so for roses as they are gross feeders and it is practically impossible to make the

soil too rich, provided all other conditions are right. The first step is to see that the soil is properly drained. If it is not so, then drainage must be provided, as roses are always injured and frequently killed by stagnant water remaining around their roots for any length of time. In the case of a single rose bed only, draining can generally be accomplished by taking out the soil to a depth of three feet, (keeping the raw subsoil by itself so that the surplus can be removed away) and placing a foot of broken stone, bricks, or coarse cinders at the bottom and filling up with the best of the soil. If this method is not found sufficient to remove surplus water, then resource must be had to tile drainage. In any case the latter is always necessary when any sized area requires draining.

The ideal soil for roses is a deep loam; if the soil is very clayey a foot of the clay subsoil should be removed and some sandy top-soil substituted. Clay soils should be made lighter, and sandy ones made heavier, according to the class of roses to be planted. The hybrid perpetuals thrive best in a clayey loam, while teas and their hybrids must have a soil which is lighter and warmer. It is therefore well when all these three classes are grown, to plant them in beds to themselves so that the soil may be so regulated as to suit the special likes of each.

In preparing the ground for roses it should be spaded and thoroughly broken up to a depth of not less than two feet where the subsoil is sandy; when the latter is clayey one may go a foot deeper with great benefit; at the same time six inches of half decayed stable, or cow manure for preference, should be incorporated with it.

The best and in fact the only practicable method of carrying out this operation is by trenching. Top soil, to the depth of a foot, is taken out of a trench eighteen inches wide across the bed and placed on one side. As rose beds, and in fact all flower beds, should be two or three inches below the surface of the walks or surrounding ground when the plants are in position and the soil has settled, it is necessary to take out three or four inches of the subsoil which should be thrown out on one side to be subsequently carried away. The manure should then be thoroughly mixed with the soil at the bottom of the trench; it is not enough merely to turn this bottom soil over in lumps but it must be thoroughly broken up and mixed with the manure. After this the top soil from the next trench should be turned over into the first trench and the work proceeded with as before. When the end of the bed is reached the top soil from the first trench is used to fill up the last one. After this trenching is completed hydrated lime, or what is better, sulphate of lime or gypsum, together with pure ground bones should be applied to the surface at the rate of half a pound of each to the square yard and worked in with a rake or hoe. This soil preparation should be done as long before planting time as possible, but the surface work should not be done when the ground is sticky. Autumn trenching is best for Spring planting, especially when the soil is at all heavy, in which case the surface work is better left until Spring, except that the lime may be spread over it at the time of spading; lime should never be spaded under.

Excepting in climates where the Winters are mild, Spring is the best time for planting, the actual date depending first upon the earliness, or otherwise, of the season; one can plant earlier in a sandy soil than in a clayey one. Dormant roses may be generally set out by the middle of April in the latitude of New York, provided conditions are suitable, but those which are not dormant and which have been wintered in pots under such conditions of temperature that their foliage has re-

mained green are best left until May, or even June, if the soil is late warming up. In planting dormant roses with roots which have not been confined in pots, holes should be wide enough to allow the roots to spread out and deep enough, if grafted stock is used, to allow the junction of the rose proper with the stock to be two or three inches below the surface. This depth may be greater in sandy soils than in clayey ones. The soil should be well firmed around the roots. Some years ago a story went the rounds of the trade to the effect that a woman who had bought a dozen or so roses from a grower, complained that they had all died but one, and this particular one her husband, whom the woman was particular to describe as a very heavy man, accidentally stepped upon. The moral of this story is that if this heavy husband had accidentally stepped upon all the roses the chances are that they would have all lived. After making the soil firm around the roots, if it is at all dry, the holes should be left open to a depth of about three

inches and filled up with water; subsequently they can be filled in and the bed finished off.

The distance apart to plant depends upon the kind; teas and their hybrids may be as close as eighteen inches, while hybrid perpetuals should not be less than two feet apart.

At planting time dormant roses should have the weak growth removed and the remainder shortened to about three buds; the cut should be made closely above an outside bud. Usually roses out of four- or five-inch pots that are in a growing condition require nothing more in the way of pruning than the removal of weak shoots.

For planting out of doors roses should not be more nor less than two years old. Never plant roses discarded from a forcing house, however low in price. Up to recent years these worn-out roses were thrown on to the dump, but they are now being sold for bedding purposes for which they invariably prove unsatisfactory.

(Concluded in April issue)

Some of the Earlier Spring Wild Flowers

FLORUM AMATOR

NOW the Spring equinox is close at hand when we have days and nights of equal length; the birds are returning from the southlands, where they have been wintering; on the southern slopes of the hillsides the green blades of grass are beginning to appear. On these slopes, in the woodlands along the banks of the full-flowing brooks, in the protected glens, and amid the rocky ravines, the pretty wild flowers are beginning to bloom.

On this bank where the soil is so thin and poor that the grass never grows luxuriantly or in this thin unfertile soil covering a flat ledge, if we get down close to the ground and look sharply enough, we may find in mid-February or early March a tiny speck, as it were, of a white flower on a little plant one to three inches high and soon succeeded by a diminutive flat oblong to lanceolate seed pod. This is the *Draba verna*, Whitlow-Grass. The flowers are really too small to pluck for a nosegay, but we sometimes gather just a few to show our friends as specimens of one of the smallest flowers which grows and that, too, on one of the smallest plants. Nevertheless this tiny plant usually unseen and down-trodden came sometime, somehow, over the stormy Atlantic from Europe.

Let us betake ourselves down into this swamp land, sparsely furnished with trees and bushes. Here we find one of the earliest, strangest looking, homeliest and most ill-smelling, yet withal one of the most interesting of the Spring flowers. This ugly flower is the *Symplocarpus foetidus*. A thick, fleshy spathe spotted and striped with yellow and purple and green encloses a large oval, fleshy spadix thickly set with small greenish-yellow and purplish flowers. The common name of this plant is Skunk Cabbage. Its odor makes it well deserve the first part of its name, and the great cabbage-like leaves which appear later than the flowers make its last name a fitting one. This is our earliest Spring flower, blooming in February and March. Its flowers by their odor even at this early date attract on warm days small flies and bees. Thoreau writing in April, 1853, speaks of seeing the bees entering the spathes of the Skunk Cabbage and

later coming out with "little yellow pellets of pollen on their thighs."

Up out of the muddy swamp land let us climb onto the rocky and thinly wooded hill side. Here we may find with its foliage half-hidden by the fallen tree leaves another March and April flower, one of the prettiest of all of them, the *Hepatica triloba*, Liverwort. The downy scapes rising out of the evergreen three-lobed leaves of the previous season are surmounted by charming flowers varying in color from blue, lavender, and pale pink to white. Of this lovely child of the early Spring the poet Lowell wrote in "The Biglow Papers":

"I, country born and bred, know where to find
Some blooms that make the season suit the mind,
An' seem to metch the doubtin' bluebird's notes,—
Half vent'rin' liverworts in furry coats."

Growing in the same location as the *Hepatica* and blooming in the same month, we find, bearing flowers of pearly white and of great beauty, the *Sanguinaria canadensis*, whose common name is Bloodroot. From the rootstock of this plant, when broken there exudes an orange-red, astringent, acrid juice from whose color this plant has received its name. A pretty and interesting feature of this flower which is borne on scapes is that the flower buds are enfolded in its leaves.

On the same rocky, wooded hillside we find two other March and April flowers. The one is *Anemone nemorosa*, variety *quinquefolia*, the Windflower, whose slender stems bearing pretty white flowers with purple-tinted edges move with every breeze. Of this flower Bryant wrote: "Gay circles of Anemones dance on their stalks." The other is the *Anemonella thalictroides*, Meadow Rue Anemone, often growing not far away from the Windflower. This plant has a leafy stem from whose top spring three to six white flowers much like those of the Windflower.

Growing on the exposed hillsides around this wooded slope, and sometimes within it, there is another March flower, the Early Saxifrage, *Saxifraga virginiana*, whose

(Continued on page 91)

Work for the Month in the Garden

SAMUEL GOLDING

*So silently but swift,
Above the wintry drift,
The long days gain and gain:—*

AND although we may still have wintry weather, there is something in the air that whispers, "The year's at the spring." Already those welcome harbingers, the Snowdrop, Crocus, and Scillas are flaunting their colors in the garden; the buds of the Forsythias are swelling, soon to break forth into gold cascades of bloom. There are signs on every side that Mother Earth is once more waking from her Winter sleep.

This forcibly reminds us that the time of gardening with pencil and paper is past, and must now be superseded by the spade and hoe, if we are to live up to resolutions formed to have the best gardens ever during the season of 1922.

The rapidly growing seedlings and vegetables in greenhouse and frames will need the most careful attention. Those from last month's sowing should be transplanted as soon as they can be conveniently handled. Flats are the best receptacles for most subjects, though egg plants and tomatoes may be exceptions, for which pots are preferable. The frames should be kept closed for a few days and shaded from bright sunshine until root action has commenced. Cultivate between the rows of growing crops and thin just enough to allow room for development. Sow more seed as often as a perfect succession demands. Regard must be paid to careful ventilation, especially during this month when we are liable to very sudden changes of temperature. Cold draughts are to be avoided as they are most detrimental to young plant life. Conserve the sun heat as much as possible by early closing during the afternoon. Maintain a nice growing atmosphere and keep all plants as near the glass as convenient to give them the benefit of light and sunshine to develop and maintain a sturdy growth and robust habit.

As soon as the frost is out of the ground and conditions will permit, no time should be lost before digging or ploughing for the earliest crops. If this was done in the Fall when one has more time to carry out any deep digging or trenching, so much the better. As I have previously remarked, this brings its own reward for the soil receives the benefit of the purifying influence of the frost. This deep digging is the mainspring of future success in growing vegetables in quantity and of quality. The light sandy soils are the best for raising early crops. They do not retain the moisture to the same degree as the heavier loam or the still more retentive clays, and therefore they are in a fit condition at an earlier date.

When ground is fit, and that will be when the soil is easily broken up with a rake, and when trodden or rolled, does not pack into a stiff or sticky mass, sow first early peas, spinach, parsnips and plant onion sets. For first peas it is advisable to sow the round seeded varieties as they are more reliable and will germinate under conditions where the marrowfats would probably not. This especially applies to heavy soils.

Give early attention to the asparagus beds and fork in a good dressing of farmyard manure, if it was not done in the Fall. If you contemplate planting asparagus

choose well prepared ground; place them in trenches about eight inches deep and two feet apart, and from three to four feet between the rows; cover with about two inches of soil. Secure two year old crowns which are generally regarded as the most satisfactory.

Remove the protecting material from strawberry beds and give a good dressing of bone meal. Tie up raspberry canes, thinning out all useless ones. Finish pruning all small bush fruit trees.

Place some strawy litter over rhubarb crowns which will help it to start into growth and protect it from late frost.

Toward the end of the month, remove wind breaks and protecting materials from around rhododendron beds and other more tender subjects; also from spring flowering plants, otherwise tulips and other bulbous stock will become drawn as do early shoots of herbaceous plants if protection is afforded too long.

Go over the rambler roses, removing all useless wood. Tie up the strongest of last year's growths, and do not overcrowd. Cut back late flowering shrubs, or those that bloom on the wood made during the current year: *Hydrangea paniculata* is one of the most common of this class of shrubs. Spring blooming shrubs must be cut back after flowering. To cut them back at this time would mean the loss of the season's bloom. Ornamental climbers will need care and should be thinned and tied up where they are required.

APRIL

During the early days of April all is activity in the vegetable garden. Arrears of digging and preparation for the reception of the crops should receive first attention. Such vegetable plants in the frames as cabbages, cauliflowers, onions, leeks, should be thoroughly hardened off before planting into their final quarters. Remove the sash on all favorable days. Give an abundance of water to crops that are growing under glass. Protect the hearts of cauliflowers from direct sunshine by breaking some leaves over the center of the plant. Keep egg plants, peppers and tomatoes moving, and allow them plenty of room in which to develop.

Make a sowing in pots of early sweet corn, lima beans, squash, and cucumbers to be planted out when the ground is warm enough. This method generally ensures a gathering of these vegetables a week or two in advance of those sown outside.

Transplant annuals from last month's sowing, using a good light compost into which plenty of leaf soil has been incorporated. Sow further batches of annuals for succession. This is a good time to sow the main plantings of Asters, Zinnias, *Phlox Drummondii*, Scabious, etc. Plant out Pansies, Sweet Williams, Foxgloves, Canterbury Bells, or other early blooming subjects that have wintered in the cold frame, as soon as favorable weather permits.

Get in a succession of peas; marrowfat varieties are generally preferred. This is one of the most important crops of the season and every effort should be made to extend its duration. Sow the main crop of onions and some early carrots and beets on a warm border. Make a planting of parsley, radishes and lettuce.

The Greenhouse, Month to Month

W. R. FOWKES

MARCH and early April are exacting periods in plant growth. Nature has aroused from her slumbers and all is active. The sunshine and extra daylight demand more attention to details.

The vinery, where the most luscious fruit is to be garnered next November, has gained new vigor. The new growths must be disbudded, but one must be careful to leave sufficient lateral growths with good eyes. Allow a little air on the top of the house all night, and avoid scalding the tender shoots. The border must be watered thoroughly and a moist atmosphere maintained inside. Check the fires early in the day, although on dull days it is policy to give brisk heat and air.

Peach and nectarines in pots that have set a good crop must be carefully disbudded. There is no mystery about this. Take away with thumb and finger every third growth, leaving enough to form next year's plant. Keep the roots well supplied with water, and the drainage should be kept clean. Give for a foliage stimulant one ounce of sulphate of iron in one gallon of water, twice a week. It will tone up the plants' systems. Syringe these plants every afternoon at three o'clock, standard time, thoroughly wetting the paths and closing the house entirely. At six o'clock open the top ventilator one or two inches, but no more. The warm afternoon treatment is conducive to rapid growth and development of the small fruits, as the June sunshine is to outdoor fruits. The open ventilators at night are the means of solidifying and resting the plant. Growth and rest are necessary in plant as well as in human life.

Palms need sufficient shading to maintain their health and vigor. They must not be allowed to become dry at the roots, and in regard to food, they like more rich fertilizer than any plant grown. Spray with ivory soap at least once a fortnight, and thus keep the plants clean of scaly pests that so disfigure the young growths and leave their hideous mark. Botanically speaking, palms together with bananas and most tufted plants are drained by the centripetal system, that is, the slope of the leaves and stems is such that the water, when applied overhead is led towards the trunk, so that syringing is not only useful but necessary. Give more air along with extra heat.

Keep young crotons clean. Avoid stimulants to get a quick growth. When the final pot is reached, plenty of plant food will benefit, but if you kill young roots now, the leaves will fall.

The last batch of strawberries in pots will require a little Clay's fertilizer to finish off their fruit. Give plenty of air and water. A shelf is a good place for them.

Pot up the early Summer batch of tuberoses. Place four bulbs in a six inch pot, using humus and cow manure. They will succeed better in this compost than in anything else.

In the orchid houses, more shade is necessary; also a little change of plants to different parts. *Lalia anceps*, having blossomed, should be hung up near the ventilators. It does not require so much water now as it will in six weeks.

Renantheras are pushing out their spikes. Keep them near the glass. Give the vandas a cool position, especially the *caerulea*, which is not often seen in good flowering condition. Too much heat and dryness is the frequent reason. Place them over a bed of oak leaves and fill the nodules with rain water every day. These plants need it more than many orchid plants. Rain water is the proper food for orchids. No stimulant is needed, as the rain has captured all the nitrogen and sulphur these plants require.

Miltonia vexillaria, commonly called *odontoglossum*, or the pansy orchid, is making rapid strides towards blooming, by strong growths that will send forth some fine spikes of bloom in May. Watch that aphid does not disfigure these beautiful plants.

Cymbidiums are easily grown, thriving best if left alone in a corner.

Chrysanthemum plants are on their way, and the exhibition kinds are now in four-inch pots. They can be kept cool as possible in a house or a cool frame; 40 degrees at night is high enough. Keep free from aphid.

Spray your carnations more than usual to keep clear of red spider. Carnation plants should be placed in cold frames ready for planting outdoors.

Tulips are now coming into their own and are arrayed in all their glory. Abundance of water and liquid manure is necessary for perfect growth.

Calla Elliottiana is a useful Summer blossomer. Its lovely yellow blooms and variegated leaves are greatly admired.

Lilium lancifolium should be started in six-inch pots. Do not use retarded bulbs of this variety as they have not proved useful, in fact, they are of no use. The same applies to gladioli. Do not use cold storage bulbs as they do not pay. Lily of the valley is, of course, all right.

Fill all empty wire hanging baskets with *Asparagus Sprengerii*.

Achimenes are also useful and make a great display. They demand much water twice daily.

Acacias are noble, hard wooded plants, liking peat soil to grow in, and the avoidance of artificial fertilizer. Their culture is quite simple. After their blooming period is past, keep cool; cut back straggly growths and syringe gently. At the end of May they can be plunged outdoors in coal ashes to the rim of the pots.

Azaleas should be given cool treatment. Soot water is a safe stimulant. You can time them for Easter blooming, and if late, they are adaptable to extra heat for forcing.

Camellias should not be excited. Be careful to keep drainage clean. Do not feed until blooms are past. Then take off all seed pods, cut out dead twigs, clean the scale off, and apply Clay's fertilizer in a liquid form the next two months while buds are formed.

Buddlia asiatica and kindred varieties should now be in four-inch pots and grown on in a good rich compost until eight or nine-inch pots are reached in order to bloom well next November.

POTASH-MARL

(Continued from page 84)

Leaf' or Chlorosis—"The name Chlorosis, or 'Yellow Leaf,' is applied to a grape disease in which the foliage turns yellow, later becoming brown. It is common in several parts of New York State but more particularly in the Central Lake District. The cause of Chlorosis is occasioned by the presence of a large amount of lime in the soil which prevents the roots from taking up a sufficient amount of iron for satisfactory growth. Experiments show that the difficulty can be overcome by applying a small amount of iron around the affected vines and plants and where the disease has occurred two years in succession a liberal application of iron around the roots as well as around the vine."

A test was made in Westchester County to determine the value of Potash-Marl as a potato fertilizer in comparison to other high grade commercial fertilizers, using equal quantities of each. The Potash-Marl-grown potatoes showed an increase in yield of over 100%. This crop was the best crop in Westchester County in 1921 and the largest and best potatoes in the exhibit of the Stamford Horticultural Society, Stamford, Conn.

An experiment was made in 1921 by the Maplewood Country Club, Maplewood, N. J., to ascertain the efficiency of Potash-Marl as a lawn dressing. The greens treated with Potash-Marl showed a luxuriant growth and this was particularly noticeable during the long dry spell in July.

The following test was made in 1920 by D. W. Bennet, of Norwalk, Conn. Two rows of *Gladiolus* beside of two rows of same planted at the same time using the same amount of commercial fertilizer and compost and Potash-Marl and compost. The two rows planted with commercial fertilizer came up with a yellow tint. The Potash-Marl treated with a darker green foliage and the spikes or foliage was a much darker green. The flowers were more brilliant and larger.

It has been found that in using Potash-Marl that the best results have been obtained by placing it directly in contact with the seed which can be safely done as there is no danger of burning.

In addition to the advantages of being odorless, and free from weed seeds, Potash-Marl does not leach away. Any of the elements necessary to plant growth which have not been consumed by the plant remain in the ground upbuilding the soil for future crops.

It has been demonstrated in many experiments made from the year 1818 to the present time that Potash-Marl as a fertilizer for crops, lawns and flowers is deserving of consideration even by the most critical.

SOME OF THE EARLIER SPRING FLOWERS

(Continued from page 88)

naked stem arising from a rosette of root leaves is surmounted by a cluster of numerous, small white flowers.

On the warm hill slopes in April there are Pussy-Toes, *Antennaria plantaginifolia*, with downy stems and woolly leaves and silky, silvery white heads of small but extremely interesting flowers. This flower was one of the earliest loves of our early childhood, and our affection for it has never grown dim.

Near the Pussy-Toes we find another of our childhood flowers, the low-growing type of the blue Violet, *Viola cucullata*. Other Violets too are found in bloom in this fickle month of April; *Viola blanda*, the Sweet White Violet, growing in the moist meadows and swamps; *Viola rotundifolia*, the Round-Leaved Yellow Violet,

which we first saw years ago growing on the clayey bank of a brook and which we have seen in bloom only once since in a like location; *Viola lanceolata*, the Lance-Leaved Violet, growing in damp ground, having white flowers whose lower petals are penciled with purple; *Viola pubescens*, the Downy Yellow Violet, whose bright yellow flowers veined with purple we have sometimes seen in open rocky woodlands in late March; *Viola canina* variety *Muhlenbergii*, Dog-Violet, which blooms shyly in late March but in profusion in April in moist, grassy, open woodlands, and whose flowers vary in color from very light to dark blue. On the dry, sandy, sunny hill-sides where the grass can barely exist there grows a Violet quite different in both flowers and foliage from the others. This is *Viola pedata*, the Bird's-Foot Violet, whose leaves are divided into many sections, and these sections again parted, and whose flowers vary in color from lilac to blue and sometimes to white. In the pretty variety of this named *bicolor*, which is much rarer than the species, the two upper petals are quite deep violet.

In the rocky, mossy, sandy soil on hill and mountain side; sometimes well down to the foot of these elevations; on the river banks or in the edges of the meadows; often in the shade of trees or shrubs, and not infrequently partly covered with the brown leaves which have fallen from the trees, we find prostrate and trailing along on the ground a little evergreen shrub which bears the sweetest scented and brightest pink flower of April. This is the Trailing Arbutus, *Epigaea repens*, which the Pilgrims called Mayflower, under which name our Whittier immortalized it in verse. The flower buds of the Trailing Arbutus are fully formed in Autumn and, protected by leaves and by snow during the Winter, burst into bloom in early Spring.

Close up to a ledge or boulder in the open country, or in a sparsely wooded ravine we find two plants whose flowers are quite different from most of those which bloom in April. The one is *Dicentra cucullaria*, Dutchman's Breeches, so called from the form of its flower, whose dainty heart-shaped white blooms tipped with yellow are borne on a scape and whose grayish green, thrice compound leaves are delicate and unusually pretty. The other is *Dicentra canadensis*, Squirrel-Corn, so called because its underground shoots bear yellow grain-like tubers. The heart-shaped blooms of this *Dicentra* are white and tipped with rose color, and its foliage closely resembles that of *D. cucullaria*.

In this same month of April in moist woodlands, growing in the clefts of the cliffs, there is another plant in flower belonging to the same order as the *Dicentras*, *Corydalis glauca*, the Pink Corydalis. The delicate pink and white flowers of this plant are borne in loose racemes and tipped with yellow, and its grayish green leaves are made up of deeply cleft leaflets with scalloped edges. This *Corydalis* continues to bloom throughout the season.

Going away from the rocky ravines and out of the woodlands into grassy places we find a dear little flower which the children all like to gather with their Violets, a flower with many common names some of which are "Innocents," "Bluets" and "Blue-Eyed Babies," but whose botanical name is *Houstonia carulea*. The flowers range in color from lilac to pale blue and sometimes to cream and have a yellow eye. They are borne on slender stems rising out of a tuft of root leaves.

Every one of these early Spring flowers and many others we have gathered in the Spring days of the years which are gone, looked upon them as objects of beauty and studied them botanically. We may not be permitted to do this again but with us the memory of these flowers ever remains.

Departments of Foreign Exchange and Book Reviews

ROSE MARÉCHAL NIEL

IN the Spring of 1870, when quite a small boy, the writer remembers going with his father one night to visit a friend who had in his greenhouse a wonderful rose in blossom, a variety which had only been "out" a few years, and was creating something of a sensation. As the night was cold we were told to make our way to the greenhouse while the owner went for a light. On opening the door we were immediately conscious of a most delicious perfume, and when the lamp was brought it revealed a room simply crowded with glorious yellow roses amid tender green foliage. Fifty years after that first introduction to Maréchal Niel no other rose has quite taken the place of this old favorite as a climber for the greenhouse.

It soon achieved a reputation as an indoor rose, and there were very few greenhouses indeed in which in the early 'seventies one was not to be found. Its productiveness, its beautiful color and form, and its delightful fragrance earned for it many admirers, and when it made its *début* in the year 1864 it marked an epoch in the rose world, crowds flocking to see it wherever it was exhibited. People who owned a greenhouse, on beholding it for the first time, were fascinated by its beauty. To see was to desire, and so it came about that for a long time Maréchal Niel held sway among roses. From the commercial standpoint it must have proved a most remunerative sort to the distributors of those days; a brisk business in the blossoms were certainly done about Easter time among nurserymen, for it was no uncommon thing to see house after house with the roofs covered with flowers.

It had not long been introduced before it began to be whispered that it was subject to canker; that it was a mistake to keep it in the house all the year, and so it came about that after it had flourished, been cut back and the new growths made, one saw this prince among roses turned out of doors for its annual airing, much the same as Azaleas and Camellias and other hard-wooded plants. That Maréchal Niel was, and is, liable to canker is a point which few who grow it to-day would dispute, but in the writer's judgment at any rate, it is largely caused through limited root-space and through over-feeding, especially where highly stimulating artificial manures are employed. In its early days many people grew it on its own root, and it was not long before the flowers were observed to be paler in color than those on the plants originally set out.

About this time some friends of ours who had suffered loss of plants through canker, obtained fresh ones, which were set in an outside border and the shoots taken through the wall and under the rafters, Vine fashion. This was followed by a larger output of blooms, and also involved more rigorous pruning after the flowering season. Another difficulty sometimes presented itself, in the debilitated state of the plant through inability to turn them out of doors for open air treatment. It was generally believed that if plants were procured on briar stocks much deeper colored flowers would result, but this could never be relied upon, although in some instances blossoms were certainly deeper in tint.

It cannot be said that Maréchal Niel was ever very popular for outdoor growing, although in certain sheltered districts to-day it is to be found growing on south walls. Its true sphere, however, is that of an indoor climber either in a house where little fire is kept or in a cold house. Outside, its flowers are not, as a rule, very freely produced or very good in size, form or color; it is when given the shelter of a roof than one sees it at its best. Splendid examples are often seen in cold houses, particularly where there is convenience for drawing the lights down on the roof or for affording abundance of air in the Summer. In a house where the conditions tend to dryness it not infrequently leads to shoots dying off, but this can be obviated to a large extent by syringing those newly planted. Another disease to which Maréchal Niel is prone is mildew; this often appears near the flowering period and is chiefly caused through ill-judged ventilation.

Possibly to-day we do not set so great a value upon this sterling sort as did gardeners of fifty years ago, and this may be accounted for by the introduction of many other climbing subjects, but if we could imagine that Maréchal Niel had to make its entrance into the rose world now would it not cause an even greater sensation than it did in the 'sixties? After all, it is unique, and one still often hears it said: "There is nothing quite like Maréchal Niel." For indoor cultivation it stands alone and has never been superseded. When well grown its half-opened buds are beautiful, its fully developed deep yellow blooms magnificent, and its foliage is a perfect setting for both, leaving nothing to be desired. To crown

all, it possesses the greatest charm which any rose can have—delicious fragrance—so sadly lacking in many more recent introductions. It is seldom seen to-day in quite the form it displayed even twenty years ago, but it is to be hoped that it will be many seasons yet before all that remains of this grand old rose is a fragrant memory.—*The Garden*.

SOME WILD ROSES

DURING the last twenty years a number of roses have been introduced from China, and although they do not command the attention bestowed on the various Hybrid Teas, they nevertheless deserve a place in every garden where space can be found for them. Wild Roses appeal to me, short though their flowering season be, for in Autumn the numerous highly colored hips produced by some species render them conspicuous and exceedingly bright at the time when most other plants are past their best. The first effect is brought about by grouping the various species in the shrubbery border, on the fringe of the wild garden, or wherever they can be allowed to ramble without much pruning. Thinning out the old growths is all the pruning they need. One of the most noteworthy is *R. Hugonis*, introduced from China by the French missionary, Peter Hugo, some twenty years ago. The single sulphur-yellow flowers, about two inches across, appear towards the end of May, the graceful arching growths being more or less clothed with blooms. The habit of the plant is semi-erect and certainly not stiff, and will attain a height of six to eight feet. It is suitable for covering large stones on the rock garden or as isolated specimens near the lawn, while it should be useful for making a hedge around a formal Rose garden. The foliage is pleasing at all times, and the flowers are followed by hips of a dark crimson color. No pruning is needed except cutting out a few of the old growths when they become crowded.

R. Willmottia.—This pretty and very distinct species was named after the well known amateur, Miss Willmott of Warley Place, and it was discovered in Western China by Messrs. Veitch's collector, Wilson, some fifteen years ago. The single rosy-carmine flowers, which are about one inch across, are freely produced during June. They are borne singly on short stems on wood of the previous year's growth. The fruits are orange-red, and the elegant foliage and arching growths add greatly to the value of a species which is quite distinct from the majority of Roses in cultivation.

R. Moyesii.—No species of hybrid of recent introduction has attracted so much attention as this delightful plant. It is quite distinct in habit, and no other Rose produces just that shade of color—it stands alone. It was first collected by Mr. A. E. Pratt about 1890 in the mountains of Szechuan at an elevation from 7,000 feet to 9,000 feet, and it was named in honor of the Rev. J. Moyes, a missionary in China. Introduced to cultivation by Messrs. Veitch in 1903, it was, when shown by them on June 9th, 1908, given an award of merit by the R.H.S. When it was exhibited by Mr. J. C. Allgrove on June 30th, 1916, it gained the coveted first-class certificate, an award thoroughly well deserved. *R. Moyesii* is quite hardy, a free grower, and will form a bush six feet to ten feet high. The flowers are about two inches across, dark red, the younger blooms being a shade of cardinal red, while an additional charm is the large cluster of tawny yellow stamens. The erect growths are covered with stout prickles, the leaves are small, and the pear-shaped orange-red hips are a decided acquisition during the Autumn months.

When *R. Moyesii* was growing at Messrs. Veitch's Coombe Wood Nursery the plants exhibited some variation in color, and the best form was figured in the *Botanical Magazine*, t. 8338. Messrs. Veitch only increased their stock from the best variety, but since the dispersal of that famous firm no doubt a number of *R. Moyesii* have been raised from seeds, and consequently inferior varieties are to be found in some gardens today.

It is increased by budding and grafting, but I think such a vigorous plant should be on its own roots, then we are not likely to be bothered with suckers. This Rose is allied to *R. macrophylla*, which is found both in China and the Himalayas.

Both *R. Moyesii* and *R. macrophylla* are at all times very noteworthy plants in the garden, but never more so than in Autumn, when their curious bottle-shaped hips change color. In *R. macrophylla* these are crowned by the very large persistent sepals. —*The Garden*.

National Association of Gardeners

Office: 286 FIFTH AVE., NEW YORK

President—Robert Cameron, Ipswich, Mass.
Vice-President—John Barnett, Sewickley, Pa.
Secretary—M. C. Ebel, 286 Fifth Ave., New York.
Treasurer—Montague Free, Brooklyn, N. Y.

TRUSTEES (For 1921) William H. Wate, Arthur Smith, D. L. Mackintosh, New Jersey; W. N. Craig, Massachusetts; H. E. Downer, New York.

DIRECTORS (To serve until 1923)—Alexander Michie, Long Island; George F. Stewart, Massachusetts; Theodore Wirth, Minnesota; George W. Hess, District of Columbia; Daniel J. Coughlin, New York; John Barnett, Pennsylvania; Montague Free, New York. (To serve until 1924)—William Gray, Rhode Island; William Hertrick, California; Albin Martini, Iowa; Thos. Hatton, Connecticut; Robert Weeks, Ohio; W. H. Griffiths, Michigan; Thos. W. Head, New Jersey. (To serve until 1925)—George Wilson, Illinois; James Stuart, New York; William Kleinheinz, Pennsylvania; John F. Huss, Connecticut; Edwin Jenkins, Massachusetts; Carl N. Fohn, Colorado; Joseph Tansey, New York.

LOCAL BRANCHES

Newport, R. I.: Andrew L. Dorward, chairman; Frederic Carter, secretary.

St. Louis, Mo.: George H. Prinz, chairman; Hugo M. Schaff, secretary.

Nassau County, L. I.: John T. Everett, Glen Cove, chairman; John McCulloch, Oyster Bay, L. I., secretary.

Boston, Mass.: Robert Cameron, chairman.

NEW SUSTAINING MEMBER

George P. Dike, of Chestnut Hill, Mass., recently became a sustaining member of the association.

NATIONAL ASSOCIATION AT FLOWER SHOW, NEW YORK

As announced in the February issue of THE GARDENER'S CHRONICLE, the association will have a booth at the International Flower Show which is to be staged from March 13 to 19 at the Grand Central Palace. All who desire information regarding the association and its activities or any subject pertaining to the gardening profession will find those in charge of the booth ready to answer questions. Circulars will be distributed briefly outlining the aims and purposes of the association and offering the services of the Service Bureau to any one desirous of employing experienced and reliable gardeners.

The Secretary's office will be glad to forward these circulars to members who desire to use them in an endeavor to interest their employers or neighboring gardeners in the association.

THE ASSOCIATION'S MEDALS

Several requests to include the association's medals among the awards for local horticulture shows have been received lately. The Secretary wishes to call attention to these medals, should members desire to include them among the awards for the various local societies.

The silver medal may be awarded for a meritorious exhibit at a horticultural show, local or national. The gold medal may be awarded for an unusual creation or novelty, or an especially meritorious exhibit. The only stipulation is that the medals must be won by members of the National Association of Gardeners.

APPLYING FOR A POSITION

The responses which came to the Secretary's office in answer to an advertisement placed by a member of the association in a New York newspaper and a farm magazine for a young man as vegetable assistant, and an assistant for a poultry department, were an education in themselves. Of the sixty or more applications which were received by mail, not more than ten gave the particulars of the applicant's experience as asked for in the advertisement; instead the applicants asked for further particulars of the position and then merely stated that they regarded themselves as fully qualified to fill the opening. There was a wide variation as to nationality, age, period of training, and experience, which was naturally to be expected, yet it was hardly anticipated that the advertisement would attract the attention of a man, who was by profession a musician, and whose wife was a concert harpist. They both had, as the applicant stated, grown vegetables for their own use at one time, and thought it would be an ideal arrangement if they could grow vegetables for the party in question during the day, and play at concerts during the evening. This is only one example of the many amusing answers received.

AMONG THE GARDENERS

M. C. Redlich secured the position of superintendent to E. P. Wempel, Grass Hopper Farm, Greenwich, Conn.

Charles Milburn secured the position of gardener to Valentine Bliss, Scranton, Pa.

Charles Thomas, who recently resigned his position as gardener on Dr. P. P. Satterwhite's estate, Great Neck, L. I., accepted a similar position on the Carrington estate, Denby Farms, Greenwich, Conn.

William Reeves has accepted the position of superintendent of the William Crawford estate, Monroe, N. Y.

John Davidson, recently of the F. F. Dryden estate, Bernardsville, N. J., has accepted the position of gardener to C. S. Sargent, Jr., Cedarhurst, L. I.

NEW MEMBERS

The following new members have recently been added to the association's membership: Thomas J. Roberts, Tarrytown, N. Y.; John Sutton, Katonah, N. Y.; George Lockhart, Lawrence, L. I.; J. Carroll Hawkes, Falmouth, Mass.; Robert Poole, Wickliffe, Ohio; James L. Wright, Atlanta, Ga.; Carl Burger, Spring Lake, Mich.; John L. Critchley, Darlings Lake, Nova Scotia; David Crawford, Jobstown, N. J.; Neil McAuley, Bernardsville, N. J.

Kunderd's 1922 Catalog

ALL who love the beautiful in gladioli (and who does not?), should have my new catalog, describing over 300 varieties. Many grand new kinds are listed this year for the first time, 19 of which are shown in their natural colors. All readers of the *Gardeners' Chronicle* no doubt know of my superior new strains, but I would especially call your attention to my new Primulinus Hybrids. These are produced by crossing with my large flowering type and are no doubt far superior to any other strains of this popular race. Because of their dainty gracefulness, Primulinus are growing in great favor as cut flowers, for none are equal to their beauty.

All gardeners strive to please their employers and you can do them no greater favor than to look into the merits of my superior varieties. Kunderd Gladioli are now so well known that you cannot afford to be without them. No strains are more popular than these, and you will be more than pleased with a fine collection of them on your grounds the coming summer.

Send for my 56 page catalog, beautifully illustrated, which is free upon request. It contains the most complete information on culture, care, storage, etc., of the Gladiolus ever written. I know that any lover of this beautiful flower will be proud to own a copy. Give me your full address and I shall gladly send you a copy, whether you wish to order any bulbs or not.

Wishing you all the most beautiful gardens you have ever grown for the coming summer, I am

Very respectfully yours,

A. E. KUNDERD, GOSHEN, INDIANA, U. S. A.

ORIGINATOR OF THE RUFFLED GLADIOLUS AND MANY OTHERS OF THE
WORLD'S MOST WONDERFUL KINDS.

The following testimonial is from a man whom all gardeners know and esteem. Mr. Craig has been the president of the National Association of Gardeners, and is one of America's foremost garden authorities.

Having purchased from A. E. Kunderd quite a large variety of gladioli, including many of the newest kinds, I am glad to state that every variety has been absolutely true to name. Mr. Kunderd has raised more fine varieties of gladioli than any other half dozen hybridists in America combined, and those who want the best obtainable, can make no mistake in ordering from him.—WILLIAM N. CRAIG, Superintendent of Faulkner Farm, Brookline, Mass.

LOCAL SOCIETIES

WESTCHESTER AND FAIRFIELD HORT. SOCIETY

The monthly meeting of the above society was held in our new home in the American Legion Hall, Port Chester, on Tuesday, February 14, and was well attended. A good start was made as there was one new member elected, and five applications received for membership. There were quite a number of exhibits including arums, lilies, antirrhinums, carnations, roses, tulips, mignonette, hyacinth stocks, sweet peas and *Primula malacoides*. George Hewitt was awarded first prize for pot of stocks; James Linane, second prize, vase of roses; James Stuart, third prize, four vases sweet peas. James Linane was awarded first prize for a display of vegetables.

An interesting letter was read from Mr. Troy who is at present visiting Australia. A committee was appointed to meet the heads of the various women's garden clubs with a view to co-operate in getting up a flower show this year for the benefit of the local hospitals. At the Fall show last year this society turned in about \$4,000 to the New Rochelle Hospital.

About seventy attended the second annual dinner, which was a great success. It was held on February 7, at the Lawrence Inn, Mamaroneck, Charles H. Totty acted as toastmaster in his usual efficient manner. We regret that through illness M. C. Ebel was unable to be with us. Among the speakers were A. Herrington, James Scott, W. C. Collins, Oscar Addor, Mr. Strange and others. Andrew Mitchell, of Greenwich, rendered some old Scotch ballads. Other singers were W. J. Collins and Harry Jones. Great credit is due to James Stuart and W. J. Sealey who made all arrangements for the dinner.

HARRY JONES, Cor. Sec'y.

TARRYTOWN HORT. SOCIETY

The regular monthly meeting of the above society was held in Masonic Hall, Feb. 15, with President T. Wilson presiding.

This was carnation night and brought forth a most meritorious lot of exhibits, both in quality and quantity, from far and near. A vase of Remington Red from G. Warburton & Sons, Fall River, Mass., which showed deeper color than Belle Washburn, with fine stem, was highly commended. From A. N. Pierson, Cromwell, Conn., a fine vase of improved Mrs. C. W. Ward, a lovely cerise pink, full flower, but stem rather weak, 70 points; a vase of crimson sport from Scott Bros., Elmsford, a much more pleasing color than Dagmar, which will undoubtedly make a mark in the future. J. Grant's prize for the best vase of 12 carnations was awarded to Wm. Jamieson, with a vase of Laddie, which were par excellence. A splendid vase of *Iris Tingitana* from J. Tansey, Tuxedo Park, caused considerable discussion. Mr. Tansey informed our President that fully 90 per cent of the bulbs flowered. Other exhibits, too numerous to mention, were all of high quality. Wm. Graham read a very clear, concise and instructive paper on the culture of carnations, which was well received.

J. W. Smith and A. D. Hutchinson were elected to active membership, and who, upon being presented to the craft, suitably responded.

W. G. WESTON, Rep. Sec'y.

SEEDS

SEED SERVICE — PLUS

FOR 121 years J. M. Thorburn & Company specialized in high-quality seeds. Their service to the American public, their quality of merchandise, their dependability is well known the country over.

For 85 years James Carter & Company of England has been supplying garden lovers everywhere with "tested" seeds under the label of "Carters Tested Seeds"—seeds selected from strong, vigorous plants, true to type and of the best strains.

We wish to announce to the American garden loving public the consolidation of these two companies. Over two centuries of seed service-ability are now united into a single organization and we are enabled to give you a service never before obtainable in this country.

The catalog of the consolidated companies is now ready for distribution.

Write us, and we will forward gladly our 1922 Garden Book.

We extend to you a cordial invitation to visit our model establishment. Prompt and courteous attention assured.

Best and Biggest Berries

"Plants That Keep Faith"—For Real Success

A dependable stock of superior small fruit plants selected from the famous collection of the country's foremost specialist in berry culture. **Supremely tasteful strawberries; large, luscious raspberries; giant, meaty blackberries; gooseberries and currants of rare flavor; splendid, heavily rooted grapes.** These and a complete stock of garden roots, fruit trees, roses, hardy perennials and other ornamental plants are listed in a fine new catalogue, No. 104, which is sent for the asking. Free advice by a berry expert to all who are interested.

J. T. LOVETT, Box 204, LITTLE SILVER, N. J.

For 44 Years a Specialist in Berry Culture.

NORTH SHORE HORT. SOCIETY

The regular monthly meeting of the above society was held in Anderson Hall, February 13. Many members came out to hear C. Elliott of Park Ridge, Ill., talk on "The General Culture of Sweet Peas." This instructive lecture was enjoyed by all, and numerous questions were asked the speaker. Plans for a large membership, both active and associate, were discussed, and a strong campaign will be made for new members. P. W. Popp of Mamaroneck, N. Y., talked on the "Flora of Florida," as he saw it in November. A vote of thanks was accorded both speakers.

R. E. KUEHNE, Cor. Secy.

AMERICAN SWEET PEA SOCIETY

The Fourteenth Annual Exhibition and Convention of the American Sweet Pea Society is to be held on June 24th and 25th, in conjunction with the Massachusetts Horticultural Society's Exhibition in Horticultural Hall, Boston, Massachusetts.

William Gray of Newport, R. I., has been appointed secretary pro tem of this society in place of E. C. Vick, who has resigned.

Here and There

RASPBERRIES AND BLACKBERRIES

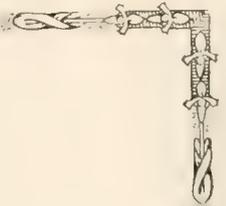

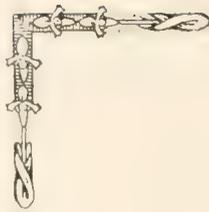

The best soil for the berries is a deep, rich, moist loam. They will not do well on wet ground, and if such a place must be used it should be well drained. It is well to use ground that has been Fall plowed, so that as soon as the ground can be worked in shape in the Spring the berries can be set out and they will begin to grow as soon as the weather gets a little warm. In this way they will have a little longer season in which to grow. Good results come, though, from work which is all done in the Spring, providing the plants are set into the ground as early as it can be well worked.

The ground should be broken deeply and pulverized well, just as though it were being prepared for a good seed bed. The best distance for planting is about six feet each way. The bushes will grow larger and more symmetrical and the berries will ripen more evenly and be larger. Some prefer planting six feet one way and three the other, but I prefer the former method, as the cultivation will be much easier and it will be easier to pick the berries.

Cultivation should begin just as soon as the plants begin to grow, or earlier if grass and weeds take a start. A light cultivator is best, but the hoe must be used sometimes to remove weeds near the plants. During the first year cultivate about once every ten days or two weeks, until the middle of July or August first. Too late cultivation keeps the plants growing and the wood does not mature sufficiently to prevent Winter killing. Mulching the plants in Winter protects them during very cold weather; it also protects the ground from heaving in the Spring, and when applied at this time, the Spring rains will soak the liquid from the manure and it will go to the roots, where it is used as food to increase, not only this year's crop but next year's growth.

Level cultivation seems best, so do not leave too much of a ridge next to the plants. It is well, after the berries are set, to level off with a hoe. During the second year they should be cultivated about once every ten days, and if the ground is dry, it is well to cultivate during the picking season. The more moist the ground is kept, the larger and fresher will be the berries.

The plants should take on a strong, self-supporting bush form and the first year's growth should be cut back to about ten

Send For The New Ten-Ten Book

It is made up of the ideas of ten leading gardeners and ten garden leaders, who were "sick and tired" (so they said) of the usual long listing catalog of seeds, plants and nursery grown things.

They all claimed that of most things, there are seldom more than ten that are worth growing, and so why bother with putting the rest of them in a catalog.

So, that's how we came to make the Ten-Ten Book the decidedly different way it is made.

Added to all the rest of the good things that are in it, are a dozen decidedly interesting tales of famous old trees.

Each is given a full page, with illustrations done in pen and ink by no less an artist than Guptil himself.

Never have our perennials been better and as for the trees and shrubs—the Winter has favored them in every way.

Send for the Ten-Ten Book. Order early and then you will surely get your early things early.

inches from the ground, during the following years all the laterals must be cut back, leaving them about 20 or 25 inches in length. This should be done as soon as the leaves or buds start in the Spring.—*Farm Life.*

SALUTE TO THE TREES

By Henry van Dyke

Many a tree is found in the wood
And every tree for its use is good:
Some for the strength of the gnarled root,
Some for the sweetness of flower or fruit;
Some for shelter against the storm,
And some to keep the hearth-stone warm;
Some for the roof, and some for the beam,
And some for a boat to breast the stream;—
In the wealth of the wood since the world began
The trees have offered their gifts to man.

But the glory of trees is more than their gifts:
'Tis a beautiful wonder of life that lifts,
From a wrinkled seed in an earth-bound clod,
A column, an arch in the temple of God,
A pillar of power, a dome of delight,
A shrine of song, and a joy of sight!
Their roots are the nurses of rivers in birth;
Their leaves are alive with the breath of the earth;
They shelter the dwellings of man; and they bend
O'er his grave with the look of a loving friend.
I have camped in the whispering forest of pines,

FINE LIMESTONE IS THE BEST

To secure best results limestone that is used for soil improvement should be finely ground. Experiments have shown that when everything is considered it is best to use material that is pulverized fine enough to pass through an eight mesh or ten mesh sieve. The Missouri College of Agriculture, through P. F. Schowengerdt, soil specialist, cautions farmers against using coarser limestone unless it is applied in such large quantities that sufficient fine material will be supplied.

It will not be profitable to use the coarse limestone and apply larger amounts unless it can be purchased for considerably less per ton than the correct size would cost. This is true because, if only three-fourths of a given quantity of material will pass through the eight mesh sieve, it will be necessary to purchase, haul and spread about one-third more ground limestone in order to get the same amount of material as desired results.—*Flower Grower.*

286 Fifth Ave. New York

This association is in no sense a trade union organization, but includes in its sustaining membership owners of some of the foremost country estates in America.

SPRAYING

is as

Essential as Fertilizing

Successful cultivation demands a knowledge of the habits of plant insects and diseases, and the proper remedies for their control.

APHINE, an effective remedy against all sap sucking insects infesting flowers, fruits and vegetables, is free of the disagreeable odors and features of most insecticides. It invigorates plant life and is unexcelled as a wash for decorative plants. Aphine will not injure the most tender flower or foliage.

FUNGINE is an excellent remedy for mildew, rust, and other blights. It is readily soluble in water and contains no sediment. Fungine does not stain the foliage but cleanses it.

VERMINE is a soil sterilizer and vermicide. It destroys cut, wire, eel and grub worms, maggots, root lice and ants, and will protect your gardens and lawns from ravages under the soil.

There is but one convincing way for you to become familiar with the merits of these products and that is to try them out for yourself. It will prove worth while.

Sold by dealers in various sizes.

J. M. Sargent and C. F. Christianson, Assistant Gardener, Prides Crossing, Miss.

“Trees have shown a wonderful response”

—the tribute of Sargent Estate Gardeners to
Davey Tree Surgery

Prides Crossing, Mass.

The Davey Tree Expert Co., Inc.,
Kent, Ohio.

Gentlemen:

The trees on Mrs. Sargent's estate have been well taken care of during the past four years by experts furnished by The Davey Tree Expert Co., and we heartily recommend the Davey Co. to any one desiring honest, conscientious tree service. The trees on this estate have shown a wonderful response to the treatment rendered by Davey's skilled experts, and we have every reason to believe that numbers of years have been added to the lives of some of our trees which under less skillful care would have been lost.

Sincerely yours,

Raymond J. Eland, *Gardener.*

Carl F. Christianson, *Ass't Gardener.*

The Most Greenhouse For The Least Money

Here is what we call our Practical Purpose House.

It will grow exactly as good stock as can be grown in any house, regardless of price.

It is just as free from repairs and will last absolutely as long as the most expensive house we build.

It differs from our regular iron frame private house construction, in having a straight eave instead of a curved one, and an angle Iron Eave Plate instead of a gutter.

The posts extend 2½ feet in the ground and are embedded firmly in concrete in-

stead of being bolted to a cast iron sill.

This is exactly the way it is done in our largest houses built for the florists, where solidity and strength are of the greatest importance.

As the posts and not the foundation wall carry the weight, the concrete wall itself extends only six inches instead of 2½ feet below the ground, which considerably reduces masonry costs.

In short, this Practical Purpose House is the most house that's practical for the least money.

Glad to send you full particulars.

A Sturdy, Powerful Grass Cutter. Built like a Tractor. Low in cost. Easiest of all to operate. Performs its work day in and day out, without expense. The only Power Lawn Mower that displaces hand mower work entirely.

Particularly Adapted to Private Estates, Park Systems, Cemeteries, Golf-Links.

Guaranteed to do more and better work at less cost and to outlast any other walking power mower of equal size. But get all the facts and see for yourself. Write today for **FREE** catalog "Lawns Beautiful." It is the best book on grass cutting ever published.

Price reduced to only \$270.00 F.O.B. here. A dealer's opportunity. Write quick.

Night-Blooming Water-Lilies

Your garden will lack both color and fragrance after nightfall unless you plan for unusual effects with Water-Lilies and other moisture-loving plants.

Make the Garden Fragrant

A dozen or more varieties, including Frank Trilobose variegated, Omarana (pink), Dentata (pale white), Kewensis (pale pink), are pictured in the 1922 color book.

Trickers's Booklet of Water-Lilies and Aquatics

Hardy and tender varieties, day and night bloomers, are carefully described. Send today for a copy of this unusual booklet.

Gardening?

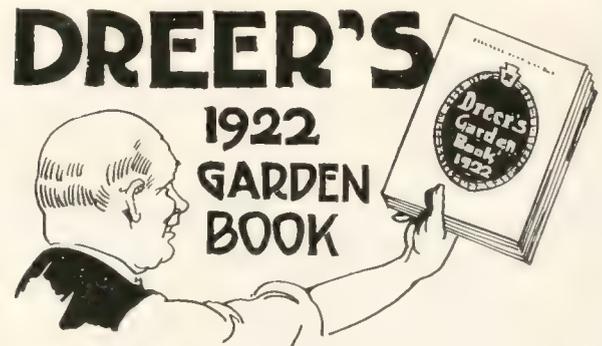

It may be a small enclosure nestled between two city yards or a wide expanse of land on an estate. It's your garden just the same. You love it. You want to put into it the loveliest flowers and arrange its paths, its beds, its shrubbery with utmost artistry.

House & Garden's BOOK of GARDENS

Is filled with the most enchanting gardens that ever nodded and flowered in the pages of *House & Garden*. Articles on flowers, shrubs and bulbs—plans and suggestions for landscape work—a complete gardener's calendar—these are some of its contents. And behind them all is the *House & Garden Information Service*, ready to answer additional questions on particular pages that interest you. Can you imagine a more delightful \$5 worth?

Make your cheque payable to

The Chronicle Press, Inc.
286 Fifth Avenue New York City

Is a reliable guide to Vegetable and Flower culture that no amateur or professional gardener can afford to be without.

The EIGHTY-FOURTH edition is larger and more complete than ever. It shows in eight color plates some of the Dreer Specialties and its 224 large pages give photographic illustrations of many of the varieties listed besides complete cultural directions for successful growing. It offers the best Vegetable and Flower Seeds; Lawn Grass and Agricultural Seeds; Garden Requisites; Plants of all kinds, including the newest Roses, Dahlias, Hardy Perennials, etc.

The Garden Book is now ready. A copy mailed free if you mention this publication.

Things and Thoughts of the Garden

MONTAGUE FREE

THOSE who are interested in alpine plants may be expected to be considerably intrigued over the possibility of new floral treasures being introduced to cultivation as a result of the Mount Everest expedition. We have not seen any reference to the matter in any horticultural paper, but an item in the N. Y. *Tribune*, culled from the London *Westminster Gazette*, would indicate that the botanical side was not neglected by the expedition. According to the *Tribune*—"The Botanical specimens included a plant belonging to the pink family from a height of 20,400 feet above sea level, several kinds of *Primula*—pale yellow, blue and dark purple—and one with big hanging bells, many gentians, a remarkable yellow *pedicularis*, *delphinium*, and some beautiful dwarf rhododendrons.

"There were 116 packets of seeds—of which 18 packets are of rhododendrons, 12 of primulas, 18 of *meconopsis*, and four gentians." This is sufficient to make a connoisseur's mouth water especially when reminded of the many valuable plants from the Himalayas that now enrich our rock gardens. *Primula denticulata*, *Gypsophila cerastioides*, *Androsace Leichtlina*, *A. sarmentosa* and many other interesting alpine all come from that region. Then there is the remarkable *Primula Winteri* that created such a furore when it was shown at the R. H. S. Hall in London ten or eleven years ago. Its large blue flowers emerging from a rosette of handsome foliage covered with white farina were something entirely distinct from those of any other *Primula*.

It was raised by Messrs. R. Gill & Son of Penryn, Cornwall, from seeds sent them from India by a Mr. Winter. As we remember it, this species was first exhibited to the public gaze in a specially constructed wire cage in the alpine house at Kew. The plants were the property of Messrs. Gill and the Kew authorities naturally did not like the idea of having such a rarity purloined—hence the cage. A most effective display was made by the raisers at the R. H. S. fortnightly show in February, 1911, when a group of magnificent specimens, many of them a foot across, were shown emerging from a background of black velvet.

In spite of its beauty one hears nothing of *P. Winteri* now—in all probability, as with many others, because its constitution is such as can be best described by that word of the gardener that expresses so much—"miffy."

* * *

We have recently been perusing a small book published in 1842 by N. B. Ward, F. L. S., entitled "On the Growth of Plants in Closely Glazed Cases."

The horticultural world owes a debt of gratitude to Mr. Ward, for, from his experiments in growing plants under close conditions, the use of "Wardian" cases for the transportation of plants over great distances was initiated.

If it were not for this invention it is reasonably sure that the introduction to cultivation of many of the plants that now grace our gardens and greenhouses would have been long deferred. Wardian cases have also played a great part in the successful introduction of economic plants from one country to another—for example, in the transportation of Para rubber, *Hevea brasiliensis*, from the western hemisphere to the east.

In these days of easy and rapid transportation it is somewhat difficult to visualize the difficulties attendant on the importation of plants in the days when ships were dependent upon the wind for their propulsion. Voyages of six or eight months' duration were by no means uncommon. Then there was the great fluctuation in temperatures experienced during the voyage, sometimes amounting to as much as a hundred degrees, that had to be taken into consideration. Even when it was possible to ship plants in a dormant condition they would be subjected to a tremendous ordeal, and it does not occasion surprise to learn that frequently shipments of plants collected at great trouble and expense were found to be dead on arrival at their destination. Menzies, to whom the botanical and horticultural world owes so much, was unfortunate in this respect. It is recorded of Menzies' last trip around the world with Vancouver, that all of his living plant collections were lost, due to the exclusion of light from them when in transit. It was customary sometimes to have someone travel with the plants in order to care for them as far as facilities would permit, and Ward makes mention of the devotion to his charge on the part of a M. de Clieux, that is most inspiring. He says: . . . "if the voyage lasts longer than usual and the water runs short, it is not every one who has the care of plants that will imitate the example of the patriotic M. de Clieux, who, in 1717, took charge of several plants of coffee that were sent to Martinico, and approved himself worthy of the trust. The voyage being long and the weather unfavorable, they all died but one; and the whole ship's company being at length reduced to short allowance of water, this zealous patriot divided his own share between himself and the plant committed to his care, and happily succeeded in carrying it safe to Martinico, where it flourished, and was the parent stock whence the neighboring islands were supplied."

By planting the material to be shipped in moist soil (cocoanut fiber refuse is sometimes successfully used nowadays) in wooden boxes glazed with glass, well protected against possible breakage—in effect a miniature greenhouse—the hazards of shipping plants long distances were to a large extent eliminated. Ward records the successful transportation of a case of plants from Sydney, Australia, to England, "and on their arrival at the docks they were in the most healthy and vigorous condition." This, in spite of the fact that the voyage lasted eight months and that the temperatures experienced on the voyage ranged from 20 degrees when rounding Cape Horn to 120 degrees when crossing the equator.

A modern instance of plants successfully enduring a long voyage was experienced at the Brooklyn Botanic Garden on the occasion of importing a shipment of rare Cycads from Australia. These plants were shipped from Australia July 29, 1914, and received at the Garden on February 16, 1915—a period of about six and a half months. The delay in this case was not due to the causes that operated in the old days but to the exigencies of war. The ship on which they were loaded at Australia was commandeered by the Federal government for the transportation of troops and the Cycads had to wait. They were reshipped and reached Port Said, when the ship was taken over by the government and the poor Cycads again dumped. They finally reached London and after another transshipment were forwarded to New York. These plants were not packed in Wardian cases but in boxes covered with stout burlap. The fact that they were in fair condition on arrival was due not so much to the method of packing as to the tenacity of life possessed by Cycads in general.

The reason that plants in Wardian cases are enabled to thrive for long periods without attention is due, of course, to the fact that there is practically no loss of water by evaporation. That which is transpired by the plants condenses on the glass and returns again and again to the soil. The great danger to guard against in Wardian cases, whether used for transportation purposes or for ornament in the home, is that of associating rampant growers with slow growing subjects, when there is the possibility of the less aggressive plants being smothered.

* * *

It seems that it was entirely by accident that Mr. Ward hit upon the principle of growing plants under close conditions. It so happened that he had placed the chrysalis of a Sphinx in moist soil in a wide-mouthed glass bottle which was covered with a tin lid. In course of time a sporeling fern (Mr. Ward consistently speaks of *seedling* ferns and fern *seeds*) and a plant of *Poa annua* developed from the surface of the soil. These flourished in the same bottle for nearly four years without any additional water. At the end of that time they died in consequence of the lid rusting, admitting rain which presumably caused them to rot.

It was apparently no trick at all to keep various species of filmy ferns alive. (It should be remembered that Mr. Ward's experiments were conducted in smoky London.) He records that *Hymenophyllum* and some mosses were planted in a bottle and that after nine years, without any additional moisture being applied, the plants were as fresh as on the day they were enclosed.

These successes evidently inspired more ambitious undertakings and a house about 8 ft. square was built outside, north of the windows facing north. This was planted with various ferns and flowering plants such as *Linnaea borealis*, *Primula vulgaris*, *Delphinium purpureum*, *Meconopsis grandis*, *Linnaea cathartica* and many others, all of which succeeded well. This house was built with a perforated

pipe around the top of it by means of which the plants could be watered. Evidently when the size of the case progresses beyond a certain limit provision must be made for watering.

The "drawing room case" was interesting, containing as it did, palms, ferns, lycopodiums, cacti and aloes. One would think that it would be rather difficult to grow in one container, plants requiring such varied conditions as these, but the difficulty was overcome by planting the moisture-loving plants in the bottom of the case and suspending the succulents from a bar in the roof and compelling them to obtain all their moisture in the form of vapor. He tells of a bottle containing *Mammillaria tenuis* and two or three fleshy species of *Euphorbia*; "The plants have been enclosed four years, the mold consisting of a very sandy loam. No water has been given since they were planted and all are in a state of perfect health although now outgrowing their narrow bounds."

Roses were grown by planting small growing varieties in tubs and covering them with bell glasses, which were somewhat smaller in diameter than the tubs. These were placed out-of-doors and they received most of their water from the rain which seeped in between the jar and the edge of the tub. These continued for three years and Mr. Ward states that they required no attention other than an occasional pruning.

These experiments led to a house being constructed, heated by hot water, which approximates very closely the greenhouse as we know it today, but presumably no provision was made for ventilating the house. The range of temperature recorded in this house in the lower part is between 45 and 90 degrees and at the top between 30 and 130 degrees. A varied collection of plants was grown, such as palms, ferns, *Calathea*, *Caladium*, succulents of various kinds, orchids, and flowering plants such as *Begonia*, *Fuchsia*, and *Passion Flower*.

* * *

It is rather amazing that Wardian cases are not used to a larger extent in growing plants in dwelling houses. There is no doubt that they achieve their purpose, if intelligence is used in the selection of plants to fill them. There is similarly no doubt that they afford an opportunity of enjoying the beauty of the plants, and the interest of growing them, to people who would otherwise be entirely deprived of this pleasure.

It would seem that there are possibilities for progressive gardeners and florists in this system of growing plants. So far the only extensive use made of it is to be seen in the Fall, when fish globes, furnished with berried plants of *Mitchella repens*, the Partridge Berry, and covered tightly with glass, are sold in the stores.

Ward evidently had great expectations concerning the value and wide applicability of his invention, some of which unfortunately have never been realized. For example in the chapter "On the application of the closed plan in improving the condition of the poor," he suggests that there are numbers of people in humble circumstances in crowded cities with a passionate love for flowers that could be gratified by making use of a Wardian case. He points out that a case can be made very cheaply and that it can be furnished still more cheaply by gathering wild plants from the woods surrounding London. Evidently he cares nothing for the feelings of the "Wild Flower Preservation Society"—if such existed in his day.

He goes on to admonish the poor and chide those responsible for the creation of "fancy" or "florists" flowers in phraseology that sounds rather quaint in these days. He will bear quoting again at this point:

"But I must here caution the poor against indulging a taste for what are called fancy flowers—things which

(Continued on page 107)

Trollius—Globe-Flower

RICHARD ROTHE

TROLLIUS is a hardy herbaceous genus of the order *Ranunculaceae* with garden forms of erect medium tall growth, distinguished by dark green, palmately lobed and dissected foliage and clear yellow or orange colored, globular or semi-globular flowers. Though generally known and easy obtainable globe flowers apparently enjoy favored and liberal space only in gardens throughout the north. Being by nature denizens of the mountainous sections and frigid regions of the northern hemisphere, they are able to endure long inclement Winters well. The rich yellow and orange hues of flowering plan-

ideal for radiant mass effects. *Trollius asiaticus* and *Japonicus* "Excelsior" produce flowers of a vivid deep orange, while those of the variety *caucasicus* "Orange Globe" are recognizable by their golden orange color. European firms list various distinct new hybrids of which the large deep yellow flowering "Gold Quelle" is obtainable in America.

Trollius Japonicus, "Excelsior"

tations conspicuously add in giving warmth to the brilliant northern color tonality, while garden owners in Middle Atlantic and Southern States reveling in a much great variety of blossoms are prone to overlook the singular charm of *Trollius*.

A strong single specimen, especially of the tall growing mixed hybrids, is strikingly beautiful. In Europe we find *Trollius* quite freely employed as choice bedding plants in formal gardens. They are also considered a highly effective material for hardy borders when grouped together in clumps of from 6 to 12 plants. Thriving best in a rich, sandy loam, they require an open sunny situation in the north. South of New England semi-shade is preferable. Not averse to moderate moisture, globe flowers are well adapted for brookside gardening and plantings along the shore lines of pond and lake.

Trollius europaeus producing medium sized loose globular flowers of clear yellow shade is the most widely known species. The fact that it is abounding within the middle and lower regions of the Alps suggests occasional employment for the rock-garden as being appropriate. For the northern climate shape and color of the flowers proves

Trollius used effectively in a border

Trollius are mostly raised from seed which is best planted right after ripening. Being very slow in germinating seeds procured by the trade should be always sown in flats during Fall. Exposed to frost and snow during Winter successful germination usually takes place the following Spring. For propagation of valuable hybrids, growers must rely on the slow process of division of old stock. *Trollius* require Winter protection in the north, leaf-covering to be preferred.

THINGS AND THOUGHTS OF THE GARDEN

(Continued from page 106)

this year are rewarded with gold medals, and the next are thrown upon the dunghill. Believing that all human pursuits ought to be estimated in exact proportion as they tend to promote the glory of God, or the good of man, let us for a moment compare the empty chase after fancy flowers with the legitimate pursuits of horticulture and floriculture. So far from the love of God, and the good of his fellow creatures, being the end and aim of the fancy florist, he values everything in proportion as it is removed from Nature, and unattainable by the rest of mankind. 'A long time must elapse ere the world can hope to see a perfect Pansy,' says one of these fancy writers. How the world is to benefit by this Phoenix when it does arrive he will of course inform us in his next publication. Let me entreat the poor to remember that their single talent should be well employed; let them learn to estimate things according to their true value, and devote their time and attention to the legitimate pursuits of horticulture and floriculture."

It is interesting to remember, in connection with this book, that present day plant ecologists are paying great attention in their investigations to evaporation, and consider it an important factor in determining the character of the vegetation.

Growing Strawberries

FLORUM AMATOR

THE soil which will grow a good crop of corn or potatoes will produce a fair crop of strawberries, but the strawberry prefers a rich and somewhat moist soil, and a sandy loam, rather than a heavy clay, though under proper culture it gives excellent results on clay land.

Though the strawberry delights in a moist soil, nevertheless it should be planted on well drained land only. It prefers a cool location. The Strawberry bed should be away from large trees, as they rob the soil of moisture, and fertility. A southern slope with buildings on the north, is favorable, when early berries are desired; otherwise a northern or western slope is to be preferred. If early varieties are planted on a southern slope, and the mulch, of which we will speak later, is removed early, and late varieties are planted on a Northern slope, and the mulch left on late, the berry bearing period will extend over a longer season. Land on which grass or strawberries have been grown within a year or two, should not be used, because the former is frequently infested with white grubs, and the latter with strawberry diseases and insects injurious to strawberries.

Stable manure is excellent, when properly used. If it cannot be obtained, sheep manure in a pulverized state, and bone meal may be used, and to these may be added a moderate amount of wood ashes.

If the strawberries are to be set out in August or September, it is a good plan to manure the land very heavily in early Spring and plant on it a hoed crop which can be harvested in July to make room for the berry plants, after the land is spaded or plowed again, in August. If the plants are to be set out in early Spring, the same method of very heavy fertilizing and raising a hoed crop the previous season should be followed. Fresh stable manure should not be used on the land just before the plants are set. If, however, the land has not been sufficiently enriched for the previous crop, the other manures previously mentioned may be applied a part on the land before it is plowed or spaded, and a part alongside of the rows of plants later. Fresh stable manure may be spread on the land in Autumn and plowed in, the land being left rough (in the furrow), so that the frost may destroy injurious grubs, etc., and the land replowed, and the plants set in Spring. If this method is followed, the land may be plowed or spaded deep. The roots of a strawberry prefer a firm rather than a loose soil; therefore, plow or spade shallow soil about six inches and deep soil about eight inches deep. Make it fine by repeated harrowings or rakings, and then make it firm with a roller or drag so that the surface may be smooth and no hollow places beneath.

The strawberry propagates itself by means of runners, which take root, and produce plants after the blooming season. These new plants will bear fruit the next season, whether they are allowed to remain in the bed or are transplanted. These rooted runners may be transplanted in early Autumn, or far better in the north in early Spring to your new beds.

Potted plants are obtained by plunging small pots under the new runners in June and July. These pots are filled with the roots by August or September, and are detached from the old plants. These pot plants are excellent for Fall settling in the home garden. The cost is greater than for rooted-runner plants taken from the beds without pots, but they are well worth the difference in cost, and are mostly used by amateur gardeners for Summer and Autumn planting. In the Spring amateurs as well as com-

mercial strawberry growers usually set out rooted runners, but of late years sometimes potted plants, which have been wintered by strawberry plant growers in cold frames, can be bought by amateur gardeners for Spring planting also.

The rows should be 30 to 36 inches apart, and the plants 18 to 24 inches apart in the row. To raise the very largest and finest berries, keep the plants strictly in hills, so that they can be cultivated on all sides, by cutting off all the runners, and allowing no young plants to form until the plants have borne one crop at least. It is more customary, however, whether potted plants are planted in Autumn or rooted runners in Spring, to allow about four to six runners to remain on each plant, and each of these to form one new plant only and to train these, as they are forming, so that they will be arranged about the parent plant like the spokes about the hub of a wheel. Another method is to train these runners along the sides of the row instead of training them in wheel form. Whichever method is used, the work is done as follows: When a young plant forms on the runners "bed it in," that is, without detaching it from the runner; plant it where you would like it to grow, and allow no more plants to form on that runner beyond the first plant, as they will if not checked. A bed of four rows with a wider space each side of it than the space between the rows to be used as a path in picking the berries and in cultivating is convenient in garden culture.

Strawberry plants should always be set out very firmly. When rooted runners are used, select such as have formed the previous Summer and which have not borne fruit; for example, rooted runners which formed in the Summer of 1916 should be used for setting out that Fall or in the Spring of 1917. They will have long whitish roots from which it is usually better to cut off with a sharp knife an inch or so.

Strawberries are divided into two classes, namely, perfect and imperfect. The flowers of the perfect have both pistils, and stamens. The flowers of these perfect varieties will produce fruit, when grown alone or with the imperfect. The flowers of the imperfect varieties have only pistils, and will not produce fruit unless they are grown with perfect varieties. In planting imperfect varieties, a perfect variety should be planted every third row or the imperfect will not bear fruit. The reason for growing imperfect varieties is that many of these bear fruit of superior size and quality. Strawberry plant catalogs always mark the varieties as perfect and imperfect.

Strawberries should be mulched in late Autumn after the ground is frozen, to protect them in Winter and prevent them from being raised out of the soil by alternate freezing and thawing of the ground. If the mulch is allowed to remain late in Spring on the plants, it will retard the crop. In regions where the snow is usually light, the mulch is most necessary, because deep snows remaining long on the ground are a good mulch. Straw or salt hay along the coast from the tidal marshes, make the best mulch. This mulch should be raked off the plants as soon as they begin to start in Spring, and either left between the rows to keep the berries clean, or better still removed altogether, and put back between the rows and plants, after they have been cultivated once or more and before the berries appear.

Strawberry plants will continue to bear berries for five or six years, but they are usually renewed after they have borne one to three crops, and the richer the land the oftener they are renewed.

Factors to Be Considered in Breeding Water Lilies

GEORGE H. PRING

BEFORE attempting the systematic breeding of water lilies the gardener should familiarize himself with the many species and present day hybrids. The taxonomy should likewise be studied so as to be able to distinguish the main groups with their respective sub-groups. If a careful study has been given the breeder will at once be able to place the species under its distinctive section by either stamens, carpellary styles or leaf characters. In most cases the gardener overlooks the botanical characteristics as unimportant for the reason that it is too theoretical. One frequently hears men discrediting the use of botany; however, it is plainly manifested that the present day student in the profession realizes the necessity of the elements of botany in the curriculum of his studies.

In studying the taxonomy of the *Nymphaea*, we find two main groups, *Apocarpic* and *Syncarpic* referring to the arrangement of the carpels or division of the seed pod. The first group *Apocarpic* has the carpels separating one from the other within the ovary, being fused only from the central axis. This fact is easily observed in *N. gigantea* by making a cross section of the ovary, the walls dividing the ovules can readily be separated. All the species under this main group are of diurnal flowering habit ranging in color from white, pink to blue. This group is again subdivided into two sections (A) *Anacaphya* which includes but one species, *N. gigantea*, native of Australia and one of the most showy of water lilies and by far the hardest to flower, where tropical Summers are lacking. The distinguishing features of this sub-group

is the absence of carpellary styles, which with other species from the innermost corona of the flower indicating the division of the ovary. (B) *Brachyceras* embracing upwards of fifteen species of world-wide distribution in the tropics. This sub-group gives us the majority of the day bloomers frequently met with in aquatic collections as *capensis*, *Zanzibariensis*, *carulea* and hybrids Whitaker, Pershing, Wilson *gigantea*, Panama Pacific, *Castaliflora*, Pennsylvania, Stella Gurney, C. W. Ward and William Stone. The distinctive characters are the prominent carpellary styles of triangular shape forming a circle upon the top of the pistil which indicates the number of seed chambers within. The anthers are long, supported upon oval filaments grading down in size to where they resemble the styles.

Group (2) *Syncarpic* is the larger of the main divisions, including both tropical and temperate species of diurnal and nocturnal flowering habit. The separation

from the first is owing to the complete fusion of the carpels on all sides, whereas the *Apocarpic* carpels were separated along the side walls. The color of the flowers vary from white, rose to purple or yellow, but no blue. The group is subdivided into three. (A) *Castalia* in which all the hardy varieties are included; this, in itself is sufficient for the layman to be able to place in its respective section. The botanical characters are the petaloid stamens, being strap-shaped, terminating with short anthers, flowers usually floating. Rhizomes, somewhat different from all other species in not being protected against drought but lying dormant throughout the Winter. There are seven species found in all of the North Temperate Zone, except the Pacific Slope of North America. (B) *Lotos*, this familiar group presents the beautiful night bloomers of our gardens. Conrad recognizes four species, *lotos*, *rubra*, *Zenkeri* and *pubescens*. The latter two I have not seen in cultivation. All the present day hybrids, including many forms, are derived from the original parentage *lotos* and *rubra*. This section is easily recognized by the vegetative characters as the prominent venation on the underside and prominently toothed edges of the leaves. In the seedling stage it is possible to place them by the elongated saggitate submerged leaves. Other factors are the large carpellary styles which are strap-shaped and bend over the pistil, the stamens are linear, wedge-shaped and rounded at the apex, not pointed as with other types. (C) *Hydrocallis* like the previous group have nocturnal flowers but instead of being supported upon stout peduncles they are floating. The notable features of this section are

Mrs. Edwards Whitaker, var. *marmorata*, presenting four floccs over one foot in diameter. (N. A. G. gold medal water lily.)

the unusually large club-shaped styles and the long hairs attached to the seeds. I have not seen any species under cultivation, but I understand one species *N. Rudgiana* was formally under cultivation in the Oaks Ames collection. Seeds of the group are used as food by the South Americans. It is manifested by these varied descriptions that there are several parts of the floral envelope, either of which may be used to classify the group or sub-group. The stamens are the easiest to use for placing the respective sections.

After studying the genus so as to become acquainted with the type material to-work with, the hybridist will decide to exert his energies in crossing night and day bloomers, with the object in mind of a perpetual blooming water lily. In reviewing the work of former hybridists the amateur will probably be somewhat enthused by Marliac's assertion that the red color in his noteworthy hybrids of hardy lilies was obtained from the *lotos* group *N.*

rubra. After a season spent in trying to intercross the day and night bloomers one will be rewarded with his notes indicating the pollinations, but alas: no seeds. My experiments have satisfied me that it is impossible to intercross between groups and likewise, so far, sub-groups. This is attested by many hundred crosses made at various times during the day and even at night. If we examine the hybrids to date we find all floral characters of one sub-group, whether it be under that of *Apocarpia* or *Syncarpia*, or in other words we do not find any trace of sub-group *Lotos* in Marliac's hybrids from group *Castalia* despite the fact that they both belong to *Syncarpia*. It is self-evident that the flesh color was transfused from within the same group from either the American or European varieties. Without doubt Marliac wanted to mislead his competitors, especially as he refused to reveal the parentage so as to prevent other water lily men at that time from crossing his field of activities.

We find statements that *N. gigantea* has been crossed with *Zanzibariensis*; this seems more reasonable in view of both types being day bloomers and native of the tropics. However, the proof is lacking except the coloration which is insufficient to substantiate the reason of stamens, styles, etc., being type. I have made repeated crosses between these sub-groups with apparent success, using *ovalifolia* as the pistillate parent. One pod produced seed of small size, resulting in a solitary seedling causing enthusiasm, so observations were noted accordingly. During the seedling stage the first disappointment appeared in the absence of spiral petioles as with normal *gigantea*. The floating leaves, however, suggested the staminate parent by being orbicular. Just as soon as the planting season opened, my coveted seedling was given a special corner in the pond. During the early part of July the first bud unfolded its floral envelope, revealing a light blue lily of the Whitaker strain. Now the question was, whether or not the blue color was sufficient evidence to prove *gigantea* as the pollen parent? No. It had to show other intermediate characters as a shortening of the carpellary styles or filamentose stamens which should naturally be the case through *gigantea* influence, but every part of the flower with the possible exception was type *Brachyceras*. Not being entirely satisfied I tried for additional proof by selling with its own pollen so as to carry the experiment through the second and third generation for possible reversion of type *gigantea* and likewise *ovalifolia*, the original parentage. The result gave forms of Whitaker and type *ovalifolia* but no possible indication of *gigantea* as the staminate parent. The reader no doubt is saying to himself, "Well, what happened?" The final experiment imparted that Nature had caused the minutest grain of pollen from *N. capensis* or *Zanzibariensis* either by wind or insects to come in contact with the pistil at the time of pollination. Motto: Be careful of undesirable pollen at the time of pollination.

PREPARING FLOWERS FOR POLLEN RECEPTION

It is plainly manifested that one cannot be too careful in plant breeding, especially so with those that are growing outside, giving free ingress to insects and wind. It is interesting to observe the hymenoptera visiting the expanded flowers for the purpose of collecting pollen and nectar. The insects in most cases visit the older flowers first by walking to and fro over the anthers, the pollen soon becoming agglutinated around their legs in round beads. When the fresh flowers are visited the reception afforded the insect is entirely different; we very soon find the insect in its death struggle trying to crawl out of its involuntary bath caused by the concave nectar-filled pistil preventing it from flying. The stamens are so arranged as to form a series of springs built in series and grading

down in size toward the center. Upon the opening of the flower all the stamens are perpendicular, making it possible for the insect to get a foothold of the small interior whorls. However, they only act as springs for the express purpose of repeatedly dumping the exhausted insect back into its involuntary bath until death. It is a common occurrence to find as many as half a dozen dead insects within the fertilized pistil. Nevertheless the flower is pollinated for the perpetuation of the species as Nature provided.

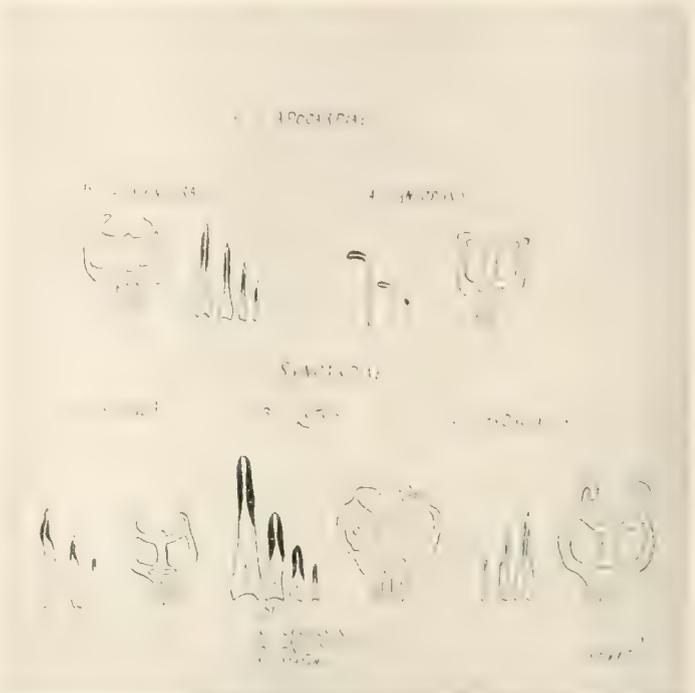

Diagram of longitudinal sections of seed pods with attached stamens, showing how the distinctive types may be recognized by either stamen or carpellary styles.

It is therefore very plain that the hybridist must be on his guard against the insect invasion of his selected flowers, and, in addition, self-pollination. To overcome the latter the seed-bearing flower should be emasculated in the bud stage by removing all stamens and attached anthers. The best time to accomplish this is at the time of flower expansion; the anthers very rarely dehisce pollen at this time. The pistil is always receptive before the shedding of pollen to prevent inbreeding. Both staminate and pistillate flowers must be covered either with waterproof bags or by the use of elastic bands to keep out pollinating insects. One cannot be too careful in this respect. I have even had insects fly into the concave pistil during the act of applying the selected pollen, immediately spoiling the cross.

OFFICIAL CATALOG OF STANDARDIZED PLANT NAMES

EXTENSION OF TIME

THE pre-publication price of \$3.50 (\$3.75 west of the Mississippi River, in Canada and abroad), is good on all orders accompanied by cash and received by May 1, 1921.

This extension of time was made necessary as it was found impossible to get out the Prospectuses to organizations in time for their members to avail of the special pre-publication price.

AMERICAN JOINT COMMITTEE ON HORTICULTURAL NOMENCLATURE.

The Peony

BERTRAND H. FARR

ITS CULTIVATION

THE cultivation of peonies is so simple and their requirements so little, that, it seems to me, their very simplicity is the most difficult point to make clearly understood. People who wish to raise extra choice exhibition blooms, often make the mistake of cuddling and overfeeding, to the extent of actual injury, instead of betterment of the plants.

I know of no class of plants that will give such great returns, for so little care and labor expended on them, as peonies. Absolutely hardy everywhere, without protection, they have only to be planted in congenial soil, where they will start off for an annual circle of bloom, increasing in beauty for many years, with no further attention than an occasional cultivation of the ground around the clumps, and a top dressing of well-rotted manure applied in the late Fall, which should be raked off of the crowns in Spring, and worked into the adjacent soil. This top dressing is not necessary as a matter of Winter protection, but the peony is a gross feeder and well repays careful feeding by increased size and abundance of bloom.

It must be borne in mind, however, that manure or strong fertilizer of any kind should never be allowed to come into direct contact with the roots. The best fertilizers are well-rotted cow manure or bone meal. Hardwood ashes used as a top dressing are also beneficial, but it is far better that no fertilizer at all be used than that it be overdone.

Any good soil, where you would reasonably expect to grow a good tomato, corn or potato plant, will grow peonies. This you would not expect to do in the vicinity of large trees or shrubs whose roots permeate and appropriate all of the moisture and nourishment of the soil. We make it a rule never to replant peonies in the same ground where they have been previously grown, unless after an interval of several years. For nursery planting, an old pasture or grass field plowed down makes an ideal location, provided there is drainage sufficient to carry off surplus water, high land being preferable to low or medium land. In a heavy clay loam the roots take a longer time to reach full maturity, but the blooms are larger, colors brighter and endure longer than in a very light, sandy or shale soil, in which the blooms come earlier, fade earlier and colors are not so intense.

PROPAGATION

The only practical way of propagating varieties of peonies is by division of the roots, separating the individual roots from the crown of the clump with a strong, sharp knife, being careful to cut so that each division has from two to three strong eyes, with two or three roots, three or four inches long, large enough to support the growth of the eyes, until a system of new roots is formed. Plant so that the eyes are two or three inches below the surface (too deep planting is injurious).

Any time in the year when the ground is not frozen, peonies may be moved successfully, except from the time the buds begin to form until the foliage is matured and the new roots complete their growth, about the middle of August. The very best time is in September and early October. The growth then is fully completed, and the roots are in a dormant state. Planted then, the new feeding roots soon begin to form, and strong roots almost invariably bloom the following June. November and December planting is perfectly safe, but bloom must not be

expected the first year, and early Spring is as good a time to plant as very late Fall. If one cannot plant in September or October, it becomes merely a matter of convenience whether to plant in Fall or Spring.

When once planted, let them alone for as many years as they seem to thrive, only dividing and replanting when the plants show indications of deterioration; unless for the purpose of increasing the stock which is another matter. For the purpose of propagating, they should be divided every third year, but for garden effect peonies usually reach perfection the fourth year, continuing in good condition several years longer, and in many instances old clumps fifteen to twenty years of age continue to thrive. As a general rule, however, eight years is about the limit.

When the clumps begin to show the necessity for replanting, it is best to start again at the beginning with small divisions of clean, smooth roots with three or four eyes, forcing the plant to begin again, and form an entirely new root system. Divisions consisting of large chunks of old crowns simply lie inactive in the ground and sometimes decay entirely. It is a common mistake to purchase old, heavy clumps, with the expectation of getting immediate effect and better results. For the first year probably one may, but never thereafter.

DISEASES

The peony has always been considered singularly free from diseases or insect pests, and to all intents and purposes, as far as the amateur is concerned, this is still true. There are two troubles, however, which within the last few years have given rise to a great deal of discussion, most of which I believe has been misleading, and since scientists at a number of experiment stations where investigations have been undertaken, do not fully agree upon the nature or the cause of the trouble, and do not suggest a remedy, I will simply state my own experiences and conclusions, which I feel sure will tend to allay any needless apprehension on the part of the amateur gardener.

In certain seasons under favorable conditions peonies are subject to fungous attacks manifested first by black spots on the leaves; second, by a blighting of the buds when half-opened, or the decaying of the half-opened buds at the base of the petals, deforming the flower; third, the extension of the fungous growth down the stem, sometimes its entire length, causing what is commonly called "stem rot," which in severe cases extends down into the roots. Sometimes the stem is first affected, causing it to "damp off" and wilt. The conditions favorable to the spread of fungus seem to be moist, humid weather, with frequent showers, followed by hot sunshine. It may be quite severe one season and disappear entirely the following season, and unless the roots themselves are affected, there seems to be no permanent injury, and it is only in a few sections where serious harm has been done, and where I believe the same soil condition and overfeeding, which I have previously explained, have something to do with it. Spraying with Bordeaux mixture as a preventative has been recommended. Where roots are badly affected it is best to replant them in perfectly fresh, sweet soil, free from manure, cutting away all affected parts.

The other trouble is variously known as "Nematodes or Eel worms," "Club roots," "Lemoine Disease," etc. There has been much discussion and difference of opin-

ion regarding these so-called diseased roots. I believe it to be more a condition than a disease; a condition brought on usually, as previously stated, by the excessive use of manure when the roots are newly planted and before they can properly assimilate the overdose. It is manifested by distorted, undeveloped roots, covered with lumpy knots and nodules. An unusual number of eyes are formed, sending up many stems of weak growth, which do not mature flower buds. This condition can also be produced by too deep planting, the use of large divisions of old worn-out roots, or by planting in a sour, pasty soil, or anything which seems to check a healthy action of the roots.

My remedy is to cut the infected roots into very small divisions of one or two eyes, shorten the roots to two to three inches, and replant in perfectly fresh soil without any manure. This forces an entirely new system of root growth, and so treated, the trouble usually disappears in a year or two. Some varieties appear to be more susceptible than others, and occasionally the trouble persists for a number of years. If these happen to be cheap kinds, it is usually better to discard them and start new with clean roots; with expensive varieties, however, it pays to have a little patience with them. Practically all the novelties from Europe that have come to us from very old gardens, are affected when we first get them, and if we are to reject them on this account, we would have to forego such wonderful varieties as *Le Cygne*, *La France*, *Mont Blanc*, etc. In fact, nearly all the fine new French varieties are more or less affected when first received, but after coming from old, worn out soil, soon outgrow this trouble when planted in new ground here. Remember, you can take the smoothest, healthiest roots from one place, plant them in a sour soil over-saturated with fresh manure, and get the most beautiful specimen of club root the following year. Fortunately it is not contagious as many have claimed, for you can plant affected roots in good soil side by side with healthy ones and I have never known a single case where the healthy roots were affected by them, which convinces me that the sick plants are simply suffering from a cause similar to what we would describe as an inactive liver or a bad case of biliousness in our own system.

To sum up, fungous attacks are local, due to weather conditions, and only occasionally seriously destructive. Clubroots are due to overfeeding, improper soil or planting, and are not contagious. Cut off and burn dead foliage in the Fall and use hardwood ashes or lime as a fertilizer for acid soil, applying manure as a top dressing only until plants are in active growth.

SUCCESSION OF BLOOM

By including the various early-flowering species, hybrids and tree peonies in one's collection, the blooming season may be extended over a period of fully two months. The tree peonies bloom quite a month ahead of the *Chinensis*, beginning early in May. As they do not die to the ground each year, they form in time woody shrubs four to five feet in height, their immense, strikingly beautiful blooms sometimes a foot in diameter; They are a wonderful sight. There are color schemes among them never found in the herbaceous section, brilliant scarlets, dark maroons and rich wine colors, delicate blush, pure pink, and art shades of mauve and violet. Most of the varieties introduced by the European growers are full-double, while a large number of the Japanese sorts are semi-double and single, with a large cushion of thick golden stamens in the center, which produces a beautiful effect.

Peony *Lutea*, a deep golden yellow single tree peony was discovered a few years ago in the Mountains of

Yunnan by the Abbe Delavay. Crosses from this were made by Lemoine with other tree peonies. One of them, *La Lorraine*, was exhibited by me at the American Peony Show in Philadelphia in June, 1917, and was given a special Award of Merit. Its blooms, six inches in diameter, are fully double and are a deep yellow. A new *Lutea* hybrid now introduced to the trade is *Souvenir du Maxime Cornu*, a deeper color with a shading similar to that in the *Mme. Edward Herriot Rose*. *Lutea* and its hybrids bloom later than the other tree peonies.

The dainty fennel-leaved Peony, *P. tenuifolia*, follows the tree peonies, and its dazzlingly brilliant scarlet flowers always attract attention. It required careful cultivation and only grows about a foot high. Next in point of interest and season of bloom are Lemoine's *Wittmanniana* hybrids, produced by crossing the pale yellow Peony *Wittmanniana*, itself a rather difficult species to grow, with *P. Chinensis*, resulting in types of strong, vigorous growths, with handsome decorative foliage and large single flowers. There are four of them: *Avante Garde*, pale rose; *Le Printemps*, creamy yellow; *Mai Fleuri*, white shaded salmon; and *Messagere*, sulphur white.

The officinalis types begin to bloom almost invariably ten days before the *Chinensis* varieties. *Officinalis rubra*, the brilliant early red of our grandmothers' gardens belongs to this species; which is a native of Europe. There is a white one, *Officinalis alba plena*, and a very beautiful large flowered pink one, *Rosca superba*, besides a number of named single and double ones not commonly seen: *Sabina*, *L'Oriflamme*, *Ourika*, and *La Brilliant* are very attractive. Most of the other species are of little interest to the average grower, but I have cut blooms of *Triternata* and *Arietina* in April, and of *Rubra superba* the 27th of June, a season of quite two months.

A MARECHAL NIEL ROSE STORY

RICHARD VINCENT, JR.

IN the Spring of '68 the writer happened in a florist's store where the proprietor was unpacking a small box of Marechal Niel roses received that morning from a grower. This rose being something wonderful at that time, the receiver of the box was wonderfully pleased at being able to obtain them for a special piece of work he had on hand. In unpacking, one of the roses was broken off at the stem, which with the others was very short and they all required stemming previous to being used; it, of course, was not lost, as it could be wired and used.

The florist having no use for the particular stem or piece of wood the writer asked and received it for use, and it was duly wrapped up and carried home. As the wood was rather hard the store-keeper smiled somewhat at the writer's request, saying, "you cannot get the stem to grow," but he guessed wrong. And why? Simply that the writer had a source that he knew not of and that was a healthy *La Marque* plant with a vigorous young shoot on it, two or three of the small buds were quickly inserted into it and one of them grew. Then the whole plant was planted out in the centre of a 60 x 30 foot greenhouse into solid bed of good soil. The way that rose grew was astonishing. In a very short time the entire roof was covered with well trained wood and it was astonishing the amount of flowers cut from same. There was scarcely any time when it was growing but that a few blooms could be cut.

We generally checked its Summer growth about the time of the first hard frost by leaving the sash open so that the frost would stop the growth and then trim and start up for a Winter crop, which was always a good

(Continued on page 124)

Roses and the Rose Garden

ARTHUR SMITH

(Continued from March Issue)

CONSIDERABLE difference of opinion exists as to which are better for outdoor planting: roses on their own roots, that is raised from cuttings, or those which have been grafted or budded, or as it is termed, "worked." Worked roses give more or less trouble by throwing up suckers from the stock upon which the rose has been worked, and some people do not distinguish the difference between the rose and the suckers, with the result that the latter frequently prevent the growth of, or kill outright, the rose. The classes of roses we are considering have only five leaflets, while the growth from the stock has seven or more leaflets and has also generally more numerous thorns. If this is borne in mind there need be no difficulty in knowing which is which.

The principal reasons for deep planting are that when the junction of the rose with the stock is well covered, the latter is not so liable to send up suckers and the stem of the rose itself will often send out roots which is a decided advantage to it. Sometimes roses are worked high, that is several inches above the roots of the stock. When this is the case and the plant is set deep enough to cover the junction, the depth of the roots is greater than it should be and the death of the plant frequently results, especially with the more tender varieties upon clayey soils. On the other hand when the junction is above the ground a heavy wind may break the rose away from the stock and the same thing may occur from being knocked by a hoe or rake. Also the union may not be perfect all round and a crack between the rose and the stock will admit air and moisture which will cause decay and the ultimate death of the plant. When a rose is upon its own roots it is less liable to Winter kill, for if it should be killed to the ground, it will invariably send up new growth from below.

Apart from any of the above reasons roses on their own roots are always more permanent than grafted ones. While there is not the slightest doubt that all the more vigorous roses do thoroughly well when grown on their own roots, there are some weak varieties which give better results *the first year or two* when grafted. As there is, however, such an abundance of good roses which are satisfactory upon their own roots, why trouble about the others, especially as there is always more dying out among grafted or budded roses in connection with the Teas and their hybrids, than own root ones? Grafting roses is no doubt the quickest method of obtaining a presentable growth by the trade for sale, and in those cases where strong growth and large blooms are wanted for one year only this way is probably better. But the lover of roses in the garden wants something more than this, and while the now more usually used *multiflora* stock is not as bad as the *manetti*, there is no doubt that for garden purposes where permanency is required, own root roses are in every way the best. It is one thing for a commercial rose grower to want a rose plant which will produce strong blooms for a year, after which he discards the plant entirely in which place the plant's length of life is of no consequence, and quite another in connection with the owner of a rose garden who wants his roses to live and produce flowers for many years.

Another important point, especially in relation to teas and hybrid teas, is that when garden roses are on their own roots it is not necessary to plant them so deeply as is generally the case when the junction of the roses with

the stock is placed several inches below the surface of the ground. This very deep planting puts the roots into soil which in the more northern states remains at a lower temperature during the growing season, at least for a more or less extensive period, than is good for the roses, and there is no doubt that a number of the least hardy roses make poor growth and ultimately die from this cause. The making of all the beautiful roses with tea blood in them to grow on a wild stock no doubt has had as much bad effect as has been the case with the grafting of all the valuable hybrid *Rhododendrons* upon the wretched *ponticum* stock.

The general climatic conditions upon which these remarks are based are those prevalent in the more northern states. In the south, however, especially in Florida, the average garden roses, and notably the teas, do better when grafted, or at least grafting does not appear to produce harm. The soil there is always warm and in sandy districts the deeper rooting habits of the *manetti* stock is some advantage in dry hot districts.

Having planted the roses in well prepared soil, success is still further assured by continually giving proper attention to cultivation, watering, pruning, and feeding. When the soil has been deeply worked and is kept cultivated watering is rarely necessary. If it should be required, mere surface sprinkling by holding a hose in the hand is practically waste of time. So long as the soil around the roots is moist no artificial watering is required, but when this soil is dry watering must be sufficient to make it moist at least to the depth of the roots, as it is only through their roots that any plants can drink. At about the end of July the beds should have a dressing of pulverized cattle or sheep manure worked into the surface.

Roses produce their flowers upon young wood; it is therefore desirable to encourage new growth as much as possible throughout the season. As far as pruning is concerned, this encouragement can be given by keeping all the dead flowers cut off and in doing so the stalk should be cut low enough; it is sufficient to leave one bud, although very strong growers may have two buds left. As the season draws to a close, and there is no longer time enough for young growth to produce flowers, this pruning may be discontinued, or merely confined to removal of seed vessels.

The time for pruning established roses in the Spring depends upon the season and the climate. It is better done a little late than too early, and it is best to wait until danger from killing frost has passed. Hybrid perpetuals may be pruned earlier than the others and in the latitude of New York these may be operated upon about the end of March. The amount of pruning is regulated by the requirements. If the object is to obtain roses of the largest possible size, irrespective of the quantity produced, they should be cut back to two or three buds, but if a mass effect and a large number of flowers are required the last year's wood may be left as long as eighteen inches or two feet, removing weak and old wood that has no strong wood growing from it. This latter system, however, will produce flowers on weak stalks and afford few flowers worth cutting, although when viewed as a mass the effect will be good.

Teas and their hybrids should have all their good strong shoots left without shortening more than one-third of their length, and any side branches cut to two eyes, removing entirely any weak growth from the center. These

should not be pruned until the buds begin to grow.

While it is especially necessary that the above three classes of roses should be grown in special beds or in a rose garden separated from other features of the ground, there are many others which are very useful for general planting and for other purposes. At the same time if one has room enough he can have his rose garden sufficiently large to grow a selection of these latter kinds as well, and along these lines a rose garden can be made into an extremely interesting museum of roses. The shrubby roses can be grown in the outside border and the climbers at the intersections of, or along the main walks.

Among these other classes the freest bloomers are the Polyantha or Baby Rambler class. These form dwarf spreading bushes suitable for use in the foreground of shrubbery, or in groups as part of a herbaceous perennial border. They produce their flowers in large sprays which are upon long enough stalks for cutting if soil is good and well prepared. As with all ever-bloomers they produce more flowers when flower stalks are kept removed.

Part of the shrubbery itself may well be devoted to roses. Some of the single wild ones are exquisite, and they are ornamental in Winter by reason of their red hips.

Among the shrubby roses the Rugosa kinds are perhaps the best known as they are very good for the purpose, being always handsome even when not in flower as their dark green leathery foliage is ever fresh-looking and their extra large fruit is extremely decorative. They make new upright growth from the roots and pruning is generally confined to removing old wood and shortening the tips of the new, to make them branch freely.

Among others, the Sweet Briar, *Rosa rubiginosa*, should always have a place found for it if possible on account of the delicious fragrance from its foliage, which is especially noticeable just after a shower. This has been hybridized with other species, and while the process has increased the size of the flowers, the fragrance from the leaves has been reduced. Most of these hybrids are, however, worth growing, as they have abundant foliage which is both vigorous and healthy. They should have plenty of room as they form large spreading bushes; pruning is confined to cutting out old wood down to the ground.

The Prairie Rose, *Rosa setigera*, produces a great profusion of single pink flowers, and is very valuable for covering dry banks, trailing over rocks, etc. The Scotch Rose, *Rosa spinosissima*, is a low shrubby kind with spreading branches; the type has pink, white and yellow flowers, and some of its numerous varieties are sometimes classed as distinct species. A very handsome free-flowering species, *R. Hugonis*, a native of western China, has yellow flowers and very ornamental deep scarlet fruit. It is extremely hardy and deserves to be more widely grown.

A very hardy kind for mixed planting is the Austrian briar, *Rosa fatida* (named for the somewhat unpleasant odor from its flowers). It is not apparent why the common name of Austrian has been given it, as it is a native of China. It does best in a dry soil where it can get plenty of air. This stands very little pruning as its flowers, which vary from yellow to coppery, are borne on the ends of the old wood. This is more interesting for distinctiveness than showiness. There are other native and exotic roses of shrubby characters which, together with those mentioned, should be made more use of in general landscape planting as tending to lift the usual shrubbery from the region of commonplace, in which much of it lies.

It is a pity that so many old-time roses which used to take such an important part in beautifying the home sur-

roundings of the early settlers, roses which they brought with them from the gardens of the old country, have been practically lost from the gardens of today.

Perhaps the sweetest of all in its perfume was the old Cabbage Rose, *Rosa centifolia*, of which a woman writer said: "Its odor is perfection, it is the standard by which I compare all other fragrances." The petals of this rose were the principal base of the also lost *pot pourri*. Another old-time rose extremely rare today is the mottled York and Lancaster. It is at least as old as the sixteenth century, and Shakespeare wrote in the *Sonnets*:

"The Roses fearfully in thorns did stand
One blushing shame, another white despair,
A third, nor red, nor white, had stol'n of both."

This York and Lancaster rose, also delightful in its perfume, was known as *Rosa mundi*—the rose of the world. A plant of it is, I believe, still growing in Hawthorne's old garden at Salem, and there is another reputed to be nearly one hundred and fifty years old in the old garden at Van Cortlandt Manor. Then there was the cheerful Cinnamon Rose with its unique perfume. There were others some of which formed small bushes, and known as Fairy Roses, all of delightful perfume, and the Sweet Briar was of course never absent. But most of these are practically vanished Roses—entirely out of cultivation.

In the evolutionary process through which roses have passed certain things have been gained in roses as flowers, while other things such as perfume, beauty of plant form itself, and permanency, have been lost. Certainly our gardens, and through them, ourselves would benefit much by the restoration of the Roses of Yesterday.

"Each morn a thousand Roses brings, you say?
Yes, but where leaves the Rose of Yesterday?"

Omar Khayyam.

Varieties of Roses—apart from species—are so numerous, especially in the garden group, that it is quite impossible to enumerate all the good ones, the few mentioned being those which the writer considers the best in each class and they are with one or two exceptions, all comparatively old and well-tried kinds. New varieties are continually being produced, some of them doomed to be soon forgotten; others which may do well in one district are of little account in others; some mildew more in one locality than they do in another a few miles away, and so on. Enthusiasts naturally desire to try out and to grow new kinds, and it is interesting to have a trial bed for this purpose. If a particular variety mildews badly it is better to discard it for one less subject to this pest, as in the worst season for mildew some are more immune than others, although it may be kept in check more or less by the use of flowers of sulphur.

In the latitude of New York and higher, it seems scarcely worth while to take up much space with Tea Roses, but when they are desired the hardiest are Etoile de Lyon, yellow; Maman Cochet, silvery rose; Maman Cochet, white, and Duchess de Brabant, pink.

Hybrid teas are the most numerous and every year brings forth new varieties. The best for bedding is undoubtedly Gruss and Teplitz. It is the hardiest and strongest growing variety of this class, sometimes attaining a height of five feet. It produces great masses of crimson flowers throughout the season. Other good ones are Mrs. Aaron Ward, dark yellow; Killarney Brilliant, deep pink; Lady Hillington, yellow; Jonkeer Mock, bright pink; Radiance, brilliant rose; Mme. Jules Grolez, satiny pink; General McArthur, bright crimson; Richmond, scarlet; Mary, Countess of Hechester, crimson; President Taft, shell pink; Ophelia, salmon pink, and Kaiserin Augusta Victoria, white.

If I had space for only one hybrid perpetual, my choice would be Paul Neyron. Its flowers are the largest of all roses, they are bright shining pink, borne in great numbers and delightfully scented. The advent of hybrid teas caused many good ones of this class to go out of cultivation by the trade, but among others, the following may still be obtained and are certainly worth growing: Captain Christy, flesh color; Frau Karl Druschki, white, much beloved of rose bugs; General Jacqueminot, velvety crimson, very fragrant; Magna Charta, rosy pink; Prince Camille de Rohan, dark velvety crimson, probably the darkest color among roses, although nearly equaled by another of its class, Black Prince, which has somewhat larger flowers but not so fragrant; and George Arends, which in all respects runs a good second to Paul Neyron.

Among climbing roses no one chooses Crimson Rambler as there are plenty of others which are in every way better, and none are as much subject to mildew. If there is only room for one it might be a toss up between American Pillar and Dr. Van Fleet, both having pink flowers and are good growers, the latter being practically mildew-proof. Among the yellows, Aviateur Bleriot is the best, closely followed by Gardenia. Today the best white is no doubt Mary Lovett; the most fragrant is probably Bess Lovett, a clear bright red; both these latter were pro-

duced by the late Dr. Van Fleet. The nearest approach to ever-blooming among the climbers hardy in the more northern states, is Vondel, which has small, apple-blossom-pink flowers.

As before stated the baby rambles and polyanthas form quite a distinct class among hybrids. Their dwarf, compact habit, with the clustered masses of bloom give them a distinction all their own, and they make very showy subjects for general garden use. The four best are, Echo, light pink; Marie Pavie, flesh pink, fragrant and lasting; Catherine Zeimet, white, and Geo. Elger, yellow.

We cannot leave unmentioned the comparatively little known Bourbon class. They require the same treatment as hybrid teas and as a rule flower more freely the latter half of the season than earlier.

The two best of those generally satisfactory for shrubby purposes, Rugosas, are, apart from the original species, the hybrids, Conrad F. Myer, bright pink, and Sir Thomas Lipton, white. Both these are more continuous bloomers than the type, but they are not quite so hardy in the districts of most severe weather without good Winter mulching. As a matter of fact all roses should be well mulched with plenty of strawy manure in Winter.

Easter Lilies

BERTHA BERBERT-HAMMOND

THE decorating of the home and the church with flowers is a popular observance in the celebration of the joyful festival of the resurrection on Easter Sunday, and while many kinds of blooming plants and fresh greenery are used, lilies are by far the flowers most favored for this purpose.

The name "Easter lily" was at one time used in connection with the lovely Madonna Lily, *Lilium candidum*. Later a lily from the islands off the coast of Japan, *Lilium longiflorum formosum*, was the type of Easter lily, but at the present time, the term is by general accord used to designate *Lilium Harrisii*, the Bermuda lily, and the most desirable of white lilies which can be obtained in bloom at the proper time for the Easter celebration. In the mild climate and the peculiar soil of the Bermuda Islands, the lilies reach perfection out-doors, and millions of potted plants are annually sent to the United States in the Spring. As the voyage is only about forty hours, cut stalks in bud packed with great care and skill can readily arrive in good condition. When promptly placed in water, they will open their handsome trumpet-shaped blooms of snowy whiteness.

Undoubtedly the Bermuda lily deserves to be called the true Easter Lily. It is probably the most exquisitely beautiful and delicately perfumed of all white lilies, and by its chaste beauty and manner of growth, peculiarly fitted to awaken reverential thoughts, not only of the revival of Nature but of the spiritual sentiment and significance underlying the celebration of Easter, the "Sunday of Joy" or the "Dominica gaudi" of ancient times. Surely it may be said that

*"We behold their tender buds expand,
Emblems of our own great resurrection,
Emblems of the bright and better land."*

-Longfellow.

Lilium Harrisii, named after but not discovered by H. K. Harris of Philadelphia, who introduced this Bermuda lily, is considered one of our most important floral

acquisitions. It is the best of all lilies for Winter forcing and for certainty and freedom of bloom, even comparatively small bulbs sending up flowers of good size and quality, though the large sized bulbs, generally preferred for growing specimen plants for decoration or exhibition, usually produce from six to eighteen flowers three to five inches long. These large, white, trumpet-shaped flowers are fragrant and retain their beauty for days.

Another delightful thing is the fact that this superb lily can readily be forced to bloom at a desired time, so that it is possible to have beautiful flowering specimens not merely at Easter, but also for Christmas, New Year, or other special occasions during the Winter, by beginning the culture four or five months before the time when the flowers are desired. This culture consists in potting very firmly a large sized bulb in rich, friable soil and covering the bulb with at least two inches of compost. A layer of charcoal should be used at the bottom of the pot to assure perfect drainage. The potted bulb should be then well watered and set in a cool place until after four or five weeks have passed, and good roots have been established. Then the potted plants, which may or may not show evidence of top growth, should gradually be exposed to sunlight. As the growth of the green sprout advances, the plant should be given as much sunlight as possible until the buds are about to open. To secure flowers that will have lasting quality, the plant should be removed from direct sunlight and copiously watered. At no time during the forcing period should the soil be allowed to become too dry; the atmosphere of the room should also be kept moist and cool. A plant forced too rapidly in a place that is too dry and hot will become spindly in growth, a good subject for insect pests, and if it develops buds at all, they are liable to blight.

The rapidity with which *L. Harrisii* may be forced into bloom is one of the points made in its favor. However, all things considered, slow development in a cool temperature is more likely to produce stronger plants and abundant flowers of fine quality.

The International Flower Show

THE Ninth International Flower Show staged at the Grand Central Palace, New York, March 13 to 19, has passed into horticultural history as one of the most wonderful flower shows ever held. Abetted by bright and clear, in fact almost Spring-like weather, the Flower Show attracted unusual numbers of visitors each day, breaking all previous attendance records on Wednesday, when more than 9,500 people, not including ticket holders, passed through the gates.

The features of the Show were naturally the garden exhibits. Two private exhibits, each covering five hundred square feet, were located at the head of the main stairway. William Boyce Thompson, Yonkers, N. Y.; Andrew Strachan, gardener, was the winner of the first prize, with a charming garden display, the background of which was formed by tall cedars. In the center a stone figure stood above a small pool surrounded by yellow

planted with *Cypripedium spectabile*, primroses, phlox, crocus, etc.

Bobbink & Atkins' garden was indeed attractive; paths divided the lawn, and led to a charming structure on the left, trimmed with rambler roses, where a small fountain played continually. Azaleas, rhododendrons, crabs, etc., formed an enormous border in the rear, in front of which were beds of azaleas to the right and left of the paths.

A splendid display of roses was made by A. M. Pierson, Inc. In the center in front of a border of conifers, rhododendrons and other flowering shrubs, stood a summer house, over which trailed rambling roses. On both sides of the path leading to the summer house were beds of roses of various varieties, Ophelia, Mme. Butterfly, Sunburst, with several beds of polyanthus roses.

A beautiful lawn bordered by various kinds of flowering shrubs was one of the most noticeable points of the F. R.

Bobbink and Atkins' garden display, awarded a gold medal.

pansies, and to which a grass path led. A mass of blooming plants, of beautiful and widely varied colors, acacias, azaleas, rambler roses, sweet peas, hyacinths, daffodils, tulips, etc., comprised the rest of the exhibit. This garden is illustrated on our cover.

The other delightful garden display was that of Mrs. Payne Whitney, Manhasset, L. I.; George Ferguson, gardener. In the foreground was a white fence and gate, from which a path led to a sun dial. Massed on both sides of the path were lupines, daffodils, hyacinths, tulips; edging the sides were *Primula malacoides* and towards the back azaleas, lilacs, etc.

In the competitive garden displays, covering one thousand square feet each, Julius Roehrs Co. carried off first honors, winning not only a gold medal, but the Garden Club of America Sweepstake prize. Tall cedars before which were rhododendrons, lilacs, forsythias, etc., formed the background. A flag-stone path led around the rock mound, which rose in the center and upon which were planted several dwarf *taxus*. Ferns were planted along the pool that was crossed by an artistic bridge. In the foreground and on the left side were other rock beds

Pierson exhibit. A group of azaleas and spiræas was planted along the edge of the lawn and a pond of water lilies placed in one corner. At the rear a path led into a bulb garden where tulips, daffodils and hyacinths were observed. This garden was backed by an unusual stone wall.

Two other exhibits, apart from the four competitive gardens, attracted wide attention; Bobbink & Atkins rock garden, which was awarded a gold medal, and the Wadley & Smythe display. In the former, a pathway led from the front of the garden to a summer house covered with ivy. The rocks were planted with favorite plants, primroses, crocuses, lilies-of-the-valley, violas, lupines, daffodils, etc. In the Wadley & Smythe display, grass paths separated the various beds which were composed of rhododendrons, kentias, geraniums, lantanas, fuchsias, etc.

Among the many plant exhibits on the main floor the groups staged by William Boyce Thompson, Andrew Strachan, gardener, and by Samuel Untermyer, Albert Millard, superintendent, were well worthy of admiration. These groups comprised a collection of foliage plants, occupying a space of 200 square feet, among which were

included orchids. Worthy of admiration also were the group of cyclamen, remarkably fine specimens, which were shown by Mrs. F. A. Constable, James Stuart, gardener, and the group of lilies, bearing enormous blooms, which were shown by Mrs. Percy Chubb, Peter Smith, gardener. The commercial plant exhibits deserving special mention were the Henry A. Dreer collection of Kurume azaleas with their wealth of bloom and range of gorgeous colors, and the Bobbink & Atkins group of *Azalea indica*, which was given a special award.

Particularly noticeable among the orchid collections were those staged by James B. Duke, Somerville, N. J., A. Miles, gardener, showing splendid specimens of cattleyas, oncidiums, cypripediums, etc., and the collection of cut orchids of cymbidiums, cattleyas, etc., by A. N. Cooley, Pittsfield, Mass., Oliver Lines, gardener, and that of J. E. Widener, Elkins Park, Pa., William Kleinheinz, gardener. The commercial orchid exhibits were excellent, too. In the large class, Joseph Manda Company had a marvelous selection of cut blooms of cymbidium hybrids, cattleyas, cypripediums, which was awarded first prize. Both George E. Baldwin & Company, and Lager & Hurrell exhibited interesting groups of cattleyas, cypripediums and cymbidiums, the former winning the honors of this class. Julius Roehrs Company was awarded first prize for its collection of orchid plants in variety, which were arranged in a most pleasing manner.

On Monday, cut flowers were not in evidence to any

great degree, either in the private or commercial classes, the garden displays being the chief attraction of the opening day of the Flower Show. Charles H. Totty Company showed the new French rose, *Souvenir de Claudius Pernet*, in color a beautiful yellow, which created quite a sensation, as did the carnations, staged by H. B. Marinelli, which were of unusually large blooms in colors of pink, rose, blush and deep mauve. The sweet peas of W. Atlee Burpee Company, varying from shades of white, pink, lavender to salmon and crimson, also attracted much attention.

While on Tuesday there was not the keen competition in the rose classes, either private or commercial, that had been anticipated, still there was an abundance of wonderful roses to draw forth words of admiration from the many visitors to the show on that day. In the five private classes, which Mrs. McK. Twombly, Convent, N. J., Robert Tyson, gardener, entered, Mrs. Twombly was awarded first prize, showing excellent blooms of *Ophelia*, *Columbia*, *Premier*, etc. In the commercial exhibits superb blooms of the rose, *Francis Scott Key*, was shown by F. R. Pierson, and their vase of *Columbia* was also very good. Wonderful blooms of *Premier* and of *Ophelia* were staged by the Duckham-Pierson Company. Two roses in particular were the center of attraction, *Souvenir de Claudius Pernet*, for which Charles H. Totty Company received a gold metal, and *Dark Pink Columbia*, for which A. N. Pierson, Inc., received a similar award.

The rock garden, exhibited by Julius Roehrs and awarded the sweepstake prize of the Garden Club of America

The classes on Wednesday were again devoted to roses. Keen competition was displayed in the table decorations, where yellow appeared to be the predominant color. In practically every entry the exhibitor used the tall vase in the center of the table with smaller vases containing the same flowers. The first prize went to Mrs. H. McK. Twombly, who decorated with Golden Ophelia; the second to T. Aitchison, who made use of Mrs. Aaron Ward, and the third to Mrs. Payne Whitney, who used the pale yellow Ophelia. Traendly & Schenck won first honors in the commercial class with a most artistic display covering three hundred square feet. Trellises covered with ivy were used for the background; the pillars supporting the baskets and vases were banked with ferns and ivy. Noticeable among the roses shown were vases of Francis Scott Key, Crusader, Premier, White Killarney, etc. The roses staged by A. N. Pierson in their attractive display, winning second honors, were Dark Pink Columbia, Ophelia, Premier, White Killarney, Crusader, etc. The stands were set off by groups of ferns to soften the arrangement. Huge bunches of Francis Scott Key, Butterfly, Ophelia, Columbia, Crusader, etc., arranged gracefully in lovely Japanese vases, formed the F. R. Pierson rose exhibit, which was given third honors. Beneath the vases, Maidenhair and *Nephrolepis* ferns were placed, producing a charming effect.

Keen contest existed on Thursday in the carnation classes for private growers. Of the ten entries for the variety "Laddie," the judges finally selected G. G. Mason, Tuxedo Park, N. Y., D. MacGregor, gardener, as the winner of the first prize. J. E. Widener, Elkins Park, Pa., William Kleinheinz, gardener, secured first honors over his competitors with a vase of one hundred fifty blooms of Laddie. Yellow was the favored color in the carnation table decorations as with the rose on the previous day, and in this class, T. Aitchison, Mamaroneck, N. Y., held first place, using the Charles H. Totty Company "Happiness." A. C. Bedford, Glen Cove, L. I., William Milstead, gardener, won second place over Mrs. Ridley Watts, who gave him a close contest. His decorations were "Enchantress Supreme" with asparagus and Maidenhair fern. Samuel Goddard, Framingham, Mass., led in the commercial class with a vase of one hundred blooms of Laddie, followed closely by Thomas Proctor, Topsfield, Mass., whose group was given a special award. In several classes the Springfield Floral Company scored first place, and among the varieties which they staged "Hope Henshaw" was prominent. This company was the only contestant in the large class, occupying one hundred fifty square feet, and their display was especially delightful with baskets and vases of "Laddie," "Enchantress Supreme," "Hope Henshaw," "Matchless," etc.

Friday witnessed a more lively contest in the sweet pea classes than last year. Unusually fine flowers, noticeable for their gorgeous colors, the strength of the stems and the size of the blooms, were shown by Mrs. W. Redmond Cross, Morristown, N. J., A. Sailer, gardener, to whom first prize was awarded. Mrs. W. D. Guthrie, Locust Valley, L. I., J. Winsock, gardener, who won second prize, showed excellent blooms of "Rose Queen," "Mrs. Kerr," etc. Of the seven competitors for the table decorations, Mrs. Ridley Watts, Morristown, N. J., Samuel Golding, gardener, won first honors, using "Mrs. Kerr" to excellent advantage in the charming arrangements of her table.

A large and attractively staged exhibit of sweet peas by W. Atlee Burpee Co., won first prize in the commercial class, Herman Mamitsch, Tenafly, N. J., winning second honors. Among the prominent varieties used in the Burpee exhibit were Mrs. Kerr, Mrs. Warren G. Harding, Flamingo, Robin Hood, Milkmaid, the latter two being awarded special certificates of merit.

A table class of miscellaneous flowers was scheduled for Saturday, William Boyce Thompson gaining first prize with scarlet nasturtiums, pansies and genistras. A bowl of iris, pussy willows, daisies and jonquils won second honors for Mrs. Ridley Watts, certainly a delightful combination.

Following are the list of awards for the Flower Show:

Plants in Flower, Private Growers

- Acacia, 3 plants, one or more varieties.—1, Mrs. F. A. Constable (James Stuart, gdr.), Mamaroneck, N. Y.
- Acacia, specimen, any variety.—1, Mrs. F. E. Lewis (J. W. Smith, gdr.), Ridgefield, Conn.
- Amaryllis, 12 plants.—1, Mrs. F. A. Constable, Mamaroneck, N. Y.; 2, D. Guggenheim (Thos. Leyden, gdr.), Hempstead House, Port Washington, N. Y.
- Amaryllis, 6 plants.—1, D. Guggenheim, Port Washington, N. Y.; 2, Mrs. F. A. Constable, Mamaroneck, N. Y.
- Azalea, specimen, any color, not less than 3 ft. in diameter.—1, Jas. A. MacDonald (R. Hughes, gdr.), Flushing, L. I.; 2, Mrs. Payne Whitney (Geo. Ferguson, gdr.), Manhasset, L. I.
- Azalea, 3 plants, any color.—1, Jas. A. MacDonald, Flushing, L. I.; 2, Mrs. E. F. Luckenbach (Thos. Teagle, gdr.), Port Washington, N. Y.
- Bougainvillea, specimen.—1, Mrs. B. G. Work (Robt. Honeyman, gdr.), Oak Knoll, Oyster Bay, L. I.; 2, Miss A. De Lamar, Pembroke Place, Glen Cove, N. Y.
- Buddleia, 3 specimens.—1, D. Guggenheim, Port Washington, N. Y.; 2, Mrs. E. F. Luckenbach, Port Washington, N. Y.
- Cineraria, 6 plants.—1, Mrs. Wm. D. Guthrie (J. A. Winsock, gdr.), East Valley, N. Y.; 2, Mrs. E. F. Luckenbach, Port Washington, N. Y.
- Cineraria stellata, 6 plants.—1, W. B. Thompson (Andrew Strachan, gdr.), Yonkers, N. Y.
- Cineraria stellata, specimen, any type.—1, Mrs. E. F. Luckenbach, Port Washington, N. Y.; 2, W. Boyce Thompson, Yonkers, N. Y.

Prizes Offered by the Secretary of the Garden Club of America

- Cyclamen, 25 plants, arranged for effect, decorative plants permitted.—1, Mrs. F. A. Constable, Mamaroneck, N. Y.; 2, D. Guggenheim, Port Washington, N. Y.
- Cyclamen, 6 plants.—1, Mrs. F. A. Constable, Mamaroneck, N. Y.; 2, D. Guggenheim, Port Washington, N. Y.
- Chorizanma, specimen.—1, Miss A. De Lamar, Pembroke Place, Glen Cove, N. Y.
- Cytisus, specimen, any variety.—1, Mrs. Chas. Mallory (W. J. Sealy, supr.), Port Chester, N. Y.; 2, Mrs. F. A. Constable, Mamaroneck, N. Y.
- Fuchsia, 1 standard, specimen.—1, Mrs. Payne Whitney, Manhasset, L. I.; 2, Miss A. De Lamar, Pembroke Place, Glen Cove, N. Y.
- Geraniums, 3 specimens.—1, Miss A. De Lamar, Pembroke Place, Glen Cove, N. Y.; 2, Mrs. Walter C. Teagle (Jas. Linane, gdr.), Glen Airrie, Port Chester, N. Y.
- Geranium, 1 standard, specimen.—1, N. F. & G. G. Brady Est. (Frank Heid, gdr.), Manhasset, L. I.; 2, Mrs. Walter C. Teagle, Glen Airrie, Port Chester, N. Y.
- Heliotrope, 3 standard, specimens.—1, Mrs. Chas. Mallory (W. J. Sealey, gdr.), Port Chester, N. Y.
- Heliotrope, 1 standard, specimen.—1, N. F. & G. G. Brady Est., Manhasset, L. I.; 2, Mrs. Chas. Mallory, Port Chester, N. Y.
- Hydrangea, 3 plants, not less than 8-in. pots.—1, Mrs. E. F. Luckenbach, Port Washington, N. Y.; 2, W. B. Thompson, Yonkers, N. Y.
- Hydrangea, specimen, not less than 8-in. pot.—1, W. Boyce Thompson, Yonkers, N. Y.; 2, Mrs. Payne Whitney, Manhasset, L. I.
- Lilac, 6 plants.—1, Miss A. De Lamar, Pembroke Place, Glen Cove, N. Y.
- Marguerite, specimen.—1, Miss A. De Lamar, Glen Cove, N. Y.; 2, Mrs. Payne Whitney, Manhasset, L. I.
- Primula malacoides, 12 plants.—1, Mrs. E. Iselin (Duncan McIntyre, gdr.), New Rochelle, N. Y.; 2, Mrs. E. F. Luckenbach, Port Washington, N. Y.
- Primula, 6 plants in variety.—1, Mrs. E. F. Luckenbach, Port Washington, N. Y.; 2, Mrs. Wm. D. Guthrie, East Valley, N. Y.
- Primulas, 6 plants in variety.—1, Miss A. De Lamar, Glen Cove, L. I.; 2, Mrs. E. F. Luckenbach, Port Washington, N. Y.
- Rhododendron, specimen, not less than 4 ft. in diameter.—1, Mrs. Harold I. Pratt (F. O. Johnson, gdr.), Glen Cove, L. I.; 2, Mrs. Walter C. Teagle, Glen Airrie, Port Chester, N. Y.

Prizes Offered by the President of the Garden Club of America

- Schizanthus, 3 plants.—1, Albert Julliard, sup't Greystone Estate, Yonkers, N. Y.; 2, Mrs. F. A. Constable, Mamaroneck, N. Y.
- Schizanthus, specimen.—1, Mrs. E. F. Luckenbach, Port Washington, N. Y.; 2, Mrs. Richard C. Colt, Garrison-on-Hudson, N. Y.
- Spiraea or Astilbe, 6 plants.—1, W. Boyce Thompson, Yonkers, N. Y.; 2, Mrs. E. F. Luckenbach, Port Washington, N. Y.
- Wistaria, specimen.—1, D. Guggenheim, Port Washington, N. Y.
- Any other specimen flowering plant.—1, Miss A. De Lamar, Glen Cove, N. Y.; 2, Mrs. B. G. Work (R. Honeyman, gdr.), Oak Knoll, Oyster Bay, L. I.
- Flowering plants covering 500 sq. ft., arranged for effect (orchids excluded), table accessories permitted.—1, W. B. Thompson, Yonkers, N. Y.; 2, Mrs. Payne Whitney, Manhasset, L. I.

Palms and Foliage Plants, Private Growers

- Aspidistra, specimen.—1, Mrs. F. A. Constable, Mamaroneck, N. Y.
- Begonia, 1 plant, specimens.—1, N. F. & G. G. Brady Est., Manhasset, L. I.; 2, Mrs. E. F. Luckenbach, Port Washington, N. Y.
- Croton, 12 plants, broad-leaved varieties.—1, Miss A. De Lamar, Glen Cove, N. Y.
- Draecena, 3 plants.—1, Mrs. E. F. Luckenbach, Port Washington, N. Y.; 2, W. B. Thompson, Yonkers, N. Y.; 3, Miss A. De Lamar, Glen Cove, N. Y.
- Kentia Fosteriana, specimen, single or bushy.—1, D. Guggenheim, Port Washington, N. Y.; 2, Mrs. F. A. Constable, Mamaroneck, N. Y.
- Kentia Belmoreana, specimen, single or bushy.—1, Mrs. F. A. Constable, Mamaroneck, N. Y.
- Phoenix Roebelenii, specimen.—1, Sterling Postley (James H. Andrews, gdr.), Oyster Bay, L. I.; 2, Mrs. F. A. Constable, Mamaroneck, N. Y.
- Palms, other than above specimen, single or bushy.—1, Mrs. F. A. Constable, Mamaroneck, N. Y.

Any specimen foliage plant, not less than four pot or tub.—1, W. Boyce Thompson, Yonkers, N. Y.; 2, Miss E. L. Luckenbach, Port Washington, N. Y.

Group of foliage plants, with orchids permitted, collection covering 200 sq. ft., arranged for effect.—1, W. Boyce Thompson, Yonkers, N. Y.; 2, Albert Millard, supt., Greystone, Yonkers, N. Y.

Ferns, Private Growers

Asparagus, specimen, any variety.—1, E. E. Smathers (W. D. Robertson, gdr.), Port Chester, N. Y.; 2, Miss A. De Lamar, Glen Cove, L. I.
 Adiantum Farleyense, or Farleyense type, specimen.—1, Mrs. E. F. Luckenbach (Thos. Twigg, gdr.), Port Washington, N. Y.; 2, James B. Duke (A. E. Miles, gdr.), Somerville, N. J.
 Adiantum any other variety, specimen.—1, E. E. Smathers; 2, Jas. A. Macdonald (R. Hughes, gdr.), Pleasantville, N. J.
 Cibotium Scheidei, specimen.—1, D. Guggenheim (Thos. A. Leyden, gdr.), Hempstead House Estate, Port Chester, N. Y.; 2, F. F. Smathers.
 Goniophlebium subauriculatum specimen.—1, Albert Millard, Greystone Estate, Yonkers, N. Y.
 Stag's Horn Fern, specimen.—1, Miss A. De Lamar, Glen Cove, N. Y.; 2, Mrs. A. Macdonald.
 Fern, any other variety, not otherwise specified.—1, Miss A. De Lamar; 2, E. E. Smathers.

Bulbous Plants, Private Growers

Freeseias, white, 12 pots or pans.—1, Bertram H. Borden (Wm. Turner, gdr.), Rumson, N. J.; 2, Mrs. Percy Chubb (Peter Smith, gdr.), Glen Cove, N. Y.
 Freeseias, colored, 6 pots or pans.—1, Mrs. Harold I. Pratt (Chas. O. Johnson, supt.), Glen Cove, L. I.; 2, Mrs. Payne Whitney (Geo. Ferguson, gdr.), Manhasset, L. I.
 Hyacinths, white, three 10-in. pots or pans.—1, Mrs. Payne Whitney; 2, Mrs. Percy Chubb.
 Hyacinths, pink or red, three 10-in. pots or pans.—1, Jas. A. Macdonald; 2, Mrs. Payne Whitney.
 Hyacinths, light blue, three 10-in. pots or pans.—1, Jas. A. Macdonald; 2, Mrs. Payne Whitney.
 Hyacinths, dark blue or purple, three 10-in. pots or pans.—1, Bertram H. Borden; 2, D. Guggenheim.
 Hyacinths, yellow, three 10-in. pots or pans.—1, Jas. A. Macdonald; 2, Mrs. Payne Whitney.
 Lilies, 12 pots, any varieties.—1, Mrs. Percy Chubb; 2, Mrs. Harold I. Pratt.
 Lily of the Valley, three 10-in. pots or pans.—1, Mrs. Payne Whitney; 2, Bertram H. Borden.
 Narcissus, 6 varieties, six 10-in. pots or pans.—1, Bertram H. Borden; 2, Mrs. Harold I. Pratt.
 Tulips, single early, 6 distinct varieties, six 10-in. pots or pans.—1, D. Guggenheim; 2, Mrs. Percy Chubb.
 Tulips, double in variety, six 10-in. pots or pans.—1, Mrs. Payne Whitney; 2, D. Guggenheim.
 Tulips, Any other variety, six or more of each distinct variety, twelve 10-in. pots or pans.—1, Bertram H. Borden; 2, D. Guggenheim.

Prizes Offered by Zandbergen Bros., Valkenburg, near Leiden, Holland, and Oyster Bay, N. Y.

Tulips, Darwin, variety Duchess of Hohenburg, 10-in. pot or pan.—1, Mrs. Payne Whitney; 2, Jas. A. Macdonald.
 Hyacinths, 10-in. pots or pans, 8 distinct varieties, one pot or pan of each.—1, Jas. A. Macdonald; 2, Mrs. Payne Whitney.

Orchid Plants, Private Growers

Twelve plants in variety, decorative plants permitted.—1, Arthur N. Cooley (Oliver Lines, gdr.), Pittsfield, Mass.

Prizes Offered by Mrs. N. F. Brady

Six plants in variety, decorative plants permitted.—1, Arthur N. Cooley; 2, Mrs. Harold I. Pratt.
 Orchids in variety, 3 plants.—1, Arthur N. Cooley; 2, Mrs. Walter C. Teagle (James Linane, gdr.), E. Port Chester.
 Brasso-Cattleya, or Brasso-Lælia, 1 plant.—1, A. N. Cooley; 2, Bertram H. Borden.
 Cattleya, Lælia, or Lælia-Cattleya Hybrid, 1 plant.—1, A. N. Cooley; 2, Mrs. Harold I. Pratt.
 Specimen plant, any variety.—1, A. N. Cooley; 2, Mrs. Walter C. Teagle.

Special Classes

These classes are open to growers who market a portion of their product, but are not engaged exclusively in the orchid business. Exhibitors in these classes are not eligible to compete in other orchid classes.
 Group of plants in variety covering 100 sq. ft., decorative plants permitted for effect.—1, James B. Duke.
 Collection of Hybrids, 25 plants, decorative plants permitted.—1, James B. Duke.

Cut Orchids, Private Growers

Collection of Cut Orchids, covering 50 sq. ft., decorative greens permitted.—1, Arthur N. Cooley.

Roses in Pots and Tubs, Private Growers

Collection of Roses in variety, covering 100 sq. ft., arranged for effect.—1, W. B. Thompson (Andrew Strachan, gdr.), Yonkers, N. Y.
 Roses, 6 Ramblers, any varieties.—1, W. B. Thompson, Yonkers, N. Y.

Cut Roses, Private Growers

Prizes Offered by Somerset Hills Garden Club of New Jersey

18 Columbia.—1, Mrs. H. McK. Twombly (R. Tyson, supt.), Convent Sta., N. J.; 2, Wm. D. Guthrie (Jas. A. Wincock, gdr.), Locust Valley, N. Y.
 18 Premier.—1, Mrs. H. McK. Twombly.
 18 Soubert.—1, Mrs. Wm. D. Guthrie; 2, Mrs. E. F. Luckenbach.
 18 Mrs. Aaron Ward.—1, Countess Mildred Hohenstein (C. I. McCormick, gdr.), Edge Hill, Pa.
 18 Ophelia, or any of its sports.—1, Mrs. H. McK. Twombly.
 18 Any white variety.—1, Howard Cole (W. R. Fowkes, gdr.), Madison, N. J.; 2, Mrs. Percy Chubb.
 18 Any other disseminated variety, pink.—1, Jas. A. Macdonald.
 18 Any other disseminated variety, yellow.—1, Mrs. H. McK. Twombly; 2, Howard Cole.
 25 One or more varieties, to be shown in one vase. Open to all Varieties, Seedlings and Sports.—1, Mrs. H. McK. Twombly; 2, Mrs. Wm. D. Guthrie.

Plants in Flower, Commercial Growers

Genista, 1 plant, specimen.—Madsen & Christensen, Wood Ridge, N. J.
 Genista, 3 standard, specimens.—1, Madsen & Christensen, Wood Ridge, N. J.; 2, A. L. Miller, Jamaica, N. Y.
 Hydrangea, 12 plants.—1, Julius Roehrs Co., Rutherford, N. J.
 Group of Azaleas, any types, covering 150 sq. ft., arranged for effect.—1, Bobbink & Atkins, Rutherford, N. J.
 Special—Open Class. An exhibit covering 1,000 sq. ft. This exhibit may include lawns, flower beds, gardens, shrubbery borders, Rose beds, bulb beds, or any exhibit that the artistic ability of the exhibitor may suggest, as the widest latitude will be allowed in this class. Special gold medals will also be awarded for special merit in this class.

Palms and Foliage Plants, Commercial Growers

Bay Trees, pyramidal, 2 plants.—1, Yonkers Nurseries, Inc., Yonkers, N. Y.
 Bay Trees, standard, 2 plants.—1, Yonkers Nurseries, Inc.; 2, Julius Roehrs Co.
 Bay Trees, columnar, 2 plants.—1, Julius Roehrs Co.
 Box Trees, pyramidal, 2 plants.—1, Bobbink & Atkins.
 Box Trees, bush, 2 plants.—1, Bobbink & Atkins.
 Kentia Forsteriana, specimen, single or bushy.—1, Yonkers Nurseries, Inc.
 Palm, other than above, specimen, single or bushy.—1, Yonkers Nurseries, Inc.; 2, Bobbink & Atkins.

Ferns, Commercial Growers

Adiantum Farleyense or its types, six plants, not less than 8-in. pots or pans.—1, A. N. Pierson, Inc., Cromwell, Conn.
 Nephrolepis, specimen, any variety.—1, F. R. Pierson, Tarrytown, N. Y.
 Cibotium Scheidei, specimen, not less than 12-in. pot or tub.—1, Bobbink & Atkins.
 Ferns, collection, not less than 50 plants.—1, F. R. Pierson.
 Ferns, specimen, any other variety.—1, F. R. Pierson.

Bulbous Plants, Commercial Growers Prizes Offered by the Rye Garden Club, G. C. A.

Lilium, 25 pots, one of each variety.—1, F. R. Pierson; 2, A. L. Miller.

Orchid Plants, Commercial Growers

Group of plants in variety, covering 300 sq. ft., decorative plants permitted for effect.—1, F. R. Pierson.
 Group of 25 plants in variety, arranged for effect, greens permitted.—1, G. E. Baldwin & Co., Mamaroneck, N. Y.; 2, Lager & Hurrell, Summit, N. J.

Cut Orchids, Commercial Growers

Collection of Cut Orchid, covering 100 sq. ft., decorative greens permitted.—1, F. R. Pierson; 2, W. O. Lutz, N. J.

Roses in Pots and Tubs, Commercial Growers

Climbing, red, specimen.—1, Louis Dupuy, Whitestone, N. Y.
 Climbing, pink, specimen.—1, A. N. Pierson, Inc.
 Climbing, yellow, specimen.—1, A. N. Pierson, Inc.
 Any single variety, specimen.—1, Louis Dupuy.

Cut Roses, Commercial Growers

50 American Beauty.—1, Gable Bros. Co., 1414 First, Washington, D. C.
 100 Columbia.—1, F. R. Pierson, Tarrytown, N. Y.; 2, L. B. Coddington, Murray Hill, N. J.
 100 Francis Scott Key.—1, F. R. Pierson.
 100 Hadley.—1, L. B. Coddington.
 100 Ophelia, or any of its sports.—1, Duckham-Pierson Co., Madison, N. J.; 2, F. R. Pierson.
 100 Premier.—1, Duckham-Pierson Co.; 2, F. R. Pierson.
 150 W. B. Thompson, any variety, specimen, supt.—1, F. B. Coddington.
 50 Crusader.—1, Duckham-Pierson Co.; 2, F. R. Pierson.
 50 Mrs. Aaron Ward.—1, Traendly & Schenck.
 50 Pike.—1, Howard A. Schenck; 2, F. R. Pierson.
 50 Sunburst.—1, W. W. Vert, Madison, N. J.
 50 Any other disseminated variety, yellow.—1, F. R. Pierson; 2, Traendly & Schenck.
 25 Any undisseminated variety. Silver Medal. A Gold Medal will also be awarded for any new variety judged worthy of the same.—1, A. N. Pierson, Inc.; Gold Medal; 2, C. H. Totty, Inc., Gold Medal.

Display Cut Roses, Commercial Growers

Display of Cut Roses, covering 300 sq. ft. and containing not less than 500 nor more than 1,000 blooms. Decorative green of any kind, including plants, permitted. Quality of bloom, artistic arrangement and general effect and variety to be considered in making award.—1, Traendly & Schenck, Rowayton, Conn.; 2, A. N. Pierson, Inc., Cromwell, Conn.; 3, F. R. Pierson, Tarrytown, N. Y.

Dinner-table Decorations, Private Growers

Table and accessories to be furnished by Flower Show Management. Table to be set for eight. Roses the only flower to be used in this decoration.—1, Mrs. H. McK. Twombly, Convent Sta., N. J.; 2, Thomas Atchison, Mamaroneck, N. Y.; 3, Mrs. Payne Whitney, Manhasset, L. I.

Special Awards for Notable Exhibits

Thomas C. Proctor, Topsfield, Mass.—100 Carnation Laddie. Silver Medal.
 Miss Ida E. Bliss, Great Neck, L. I.—Salmon Salvia splendens. Certificate of Merit.
 J. B. Duke, Somerville, N. J.—Cattleya Enid var. Mrs. Warren G. Harding. Silver Medal.
 Joseph Manda Co., West Orange, N. J.—Cymbidium hybrid. Gola Medal.
 Mrs. W. C. Teagle, Port Chester, N. Y.—Pyramid Box trees. Cultured certificate.
 N. F. & G. Brady Estate, Manhasset, L. I.—Carnations Merveille Francaise and Le Miracle. Cultural Certificates.
 Countess Mildred Hohenstein, Edge Hill, Pa.—Yellow seedling Rose. Silver Medal.
 A. L. Miller, Jamaica, L. I.—Group of pot plants. Gold Medal.
 B. H. Borden, Rumson, N. J.—Three spikes Cymbidium hybrids. Silver Medal.
 Miss Marshall, Coe Estate, Oyster Bay, L. I.—Collection of cut Camellias. Silver Medal.
 C. H. Mackay, Roslyn, N. Y.—New white Snapdragon. Certificate of Merit.
 A. N. Cooley, Pittsfield, Mass.—Cattleya Cissie. Gold Medal.

The Fruit Garden

HOWARD N. SCARFF

OF YOU who are fortunate enough to possess your own garden, who has not felt the thrill of joy and satisfaction in the height of strawberry season to find your own vines loaded with this luscious fruit? You picked a basketful and served them with cream, or perhaps in a shortcake, for dinner, and truly you never tasted berries of such delightful freshness and such delicious flavor. They did not have that soggy, sluggish taste as those from the market which were picked several days before and which have lost their fine delicate flavor and texture from exposure to the hot sultry atmosphere. But the greatest satisfaction is not derived from this almost super-flavor of the fruit. It is the fact that you have planted the patch with the utmost care, guarded it through its infancy, keeping the soil well cultivated, and whenever spare time would permit, dealing the death blow to every weed that came into view. You have seen the plants respond to this care; you have watched the growth start with increased vigor on the addition of a little fertilizer. Then through the cold bleak months, as these little plants nestled snugly under their Winter mulch, they kept you in mild anxiety and anticipation as to what joy they might bring you for your effort spent. Now as you stand in the midst of this little garden, whose every breath is filled with the delicate aroma of the ripening fruit hanging in the clusters on the vines at your feet, you feel the fascination and joy that comes to all who have secured good results from their fruit garden.

BUSH FRUITS

Strawberries are just one of the delicacies such a garden will produce. Where space permits you will usually find a row or more of raspberries, the blackcaps with their clusters of pearly black fruit conspicuous among the green and grey of the foliage or the Reds showing dull amber in the sunlight. Many of us are staunch friends of the sturdy blackberry. Their late bearing brings them at a time when most of the other bush fruits are gone. The sweet juicy flavor of these is never so good as when just picked from the bush. Perhaps none other of the so called small fruits attracts the birds as does the blackberry; although I believe that all garden lovers are bird lovers even if the birds do steal a few of the cherished fruits. The trailing vines of the dewberry produce large juicy fruit similar to the blackberry, yet larger and sweeter and with but little core. They make an excellent sweet wine besides their fine dessert qualities, and are gaining in popularity in some sections. Currants and gooseberries were always found in the older gardens until a troublesome little worm infested the bushes stripping them of their leaves and thus resulting in an inferior crop of fruit. Now this pest can be so easily controlled with insecticides that we need never omit them from our plantings. Their culinary value for making pies and jellies cannot be overestimated.

THE EVERBEARERS

The Fall-bearing varieties of strawberries and raspberries lengthen the productive period of our gardens even until checked in the Autumn by frost. The superb and progressive strawberries seem to give the greatest satisfaction of this class and will bear both a Spring and a Fall crop, although the latter will be much better if the Spring blossoms are pinched off. Of the raspberries, St. Regis has been the standard everbearer. It produces a

Spring crop ripening nearly a week before the other varieties, continuing to bear more or less until Fall. Erskine Park, a newer variety, will produce perhaps the heaviest Autumn crop of all. The LaFrance is coming into prominence because of its strong canes and large fruit. All of these everbearing sorts are greatly improved by a little irrigation during the hot, dry, Summer months.

GRAPES AND LOGANBERRIES

Trained to the fence around the garden what could be more fitting and also more economical than a few grape vines. Most of us know grapes only from the "Concords" we buy on market, which are greatly inferior to some of the better varieties we may grow at home, such as the Worden, a large blue variety; Caco, an exceptionally good and new red, large and fine flavored; Diamond and Niagara are both fine white grapes. I do not believe any fruit is so relished when taken directly from the vine as the grape, and I will assure you they will taste doubly good to those of you who can pluck a bunch from a vine you yourself have planted and cared for. If you are fortunate enough to live in the tropical climate of the Pacific Coast you may enjoy the Loganberry of which so much has been said during the past few years, and the Himalaya berry, the finest of all bush fruits, as one grower claims. I do not believe that either of these has been grown successfully out of doors in the Middle West or in the East.

BLUEBERRIES

The U. S. Dept. of Agriculture is improving the blueberry with such success that it will only be a matter of a short time until we can have plants from these choice new varieties for our gardens. The extra large berries of almost melting sweetness are a very marked improvement over the common wild sorts.

TREE FRUITS

Let us not overlook the tree fruits. It takes a little longer to grow this class but the reward is much greater. The apple is king of all fruits and we are learning more and more of its value in our every day diet. With just a little care we can grow them just as fine as our Western boxed apples, and who would not be proud to own a half dozen or more of these trees that were loaded with perfect fruit, the result of our efforts at just odd times? Now there are the cherries, peaches, plums, pears, quinces, apricots and many others. We hardly know the value and fascination of these fruits until we have grown them ourselves, solved the sometimes perplexing problems they have presented to us, combated all of their enemies and then see these faithful trees start bearing and more than surpass our greatest expectations. There is perhaps no other fruit whose quality is lowered to such a great degree by its commercial handling as is the peach. In the first place, the commercial varieties grown must be of firm flesh to stand up under transportation without undue injury, and it happens that most of these particular varieties are far from being our finest flavored peaches. Secondly, they must be picked when still immature to prevent them from becoming over ripe before being sold to the consumer, and thus giving them a flat lifeless taste. In our gardens we may plant the sweeter, juicier varieties and allow them to soften to mellow ripeness before picking and thus get one hundred per cent of the flavor.

(Continued on page 124)

Arctic and Alpine Vegetation

WILLARD N. CLUTE

THE tilt given to the axis of our planet when it began its everlasting spin about the sun is responsible for a great deal of that variety with which life is said to be spiced. Among other things it gave us our seasons and incidentally that succession of storms and calms that we call the weather. On a globe with its axis perpendicular to the plane of its orbit, every place on its surface would receive the same length of daylight in the twenty-four hours, but the greatest intensity of light and heat would be at the equator from whence it would decrease regularly to the poles. The inclined axis of our own globe, however, makes the sun appear to travel north and south with the seasons over a region forty-seven degrees wide, at one time carrying Summer conditions far northward and at another leaving a vast region about the pole in cold and darkness while it advances Summer toward the opposite pole.

Under these conditions the vegetation near the equator enjoys perpetual Summer, interrupted only by wet and dry seasons as the sun passes with its belt of clouds, while the plants nearer the poles must adjust themselves to great changes, now exposed to the terrible cold and darkness of the long arctic night and now bathed in sunlight for weeks at a time. In latitude 70° the sun in Summer is above the horizon continuously for sixty-five days and in latitude 80° it shines uninterruptedly for one hundred and thirty-four days. The decrease in the heat and light intensity in high latitudes is compensated for, in some degree, by the greater length of daylight. At mid-Summer more heat falls on the polar regions in twenty-four hours than falls on the equator in the same time, but in spite of this the lower layers of the soil remain in the condition they were left in after the last glaciation and have never thawed out. Much of the heat that reaches the earth is used in thawing the upper layers of soil, in melting the ice and snow and in evaporating the water, so that the soil is never really warm. Evaporation, however, is not rapid and in spite of a reduced rainfall the soil over vast areas is wet or boggy. Where drainage is poor, the water stands in puddles between peaty hillocks on which the scanty vegetation grows.

A broad belt of this nature forms the northern limit of vegetation in both hemispheres and is known as tundra. In its more favorable sections it may support a plant covering of grasses and flowering plants, but elsewhere it is covered with mosses, especially peat mosses, and lichens like the "reindeer moss" (*Cladonia*) which affords food for musk oxen, reindeers and other herbivores.

The most noticeable effect that cold produces on plants is a reduction in size. The plants that inhabit cold regions are always small and compact in comparison with the same species from more hospitable lands. Great numbers of "cushion-plants" with minute leaves and short stems densely matted together are found and these, growing in close little communities, form the bloom mats so frequently mentioned in descriptions of northern countries. The flowers for the most part are large, brilliantly colored and abundant, and stem and leaves often have considerable color also. Many forms are in demand for the rock garden in milder regions. Most of the species whose common names begin with "arctic" belong to this class.

Owing to the shortness of the Summer season in high latitudes there is no succession of bloom such as we see in milder regions. When Spring comes all vegetation

pushes forth with astonishing rapidity and is soon in full leaf and flower. A remarkably small amount of heat is able to induce growth, a few degrees above the freezing point being sufficient. Frosts may occur at any time during the Summer and the plants be frozen up again and again, but such hardy specimens thaw out again and continue growth unharmed. The woody plants find it extremely difficult to survive such conditions and usually drop out long before the limits of vegetation are reached. Last to give up the struggle are the aspens, birches, alders, and willows. Reduced in stature to the size of small shrubs or undershrubs they make a brave stand but finally only the willows are left and these literally digging themselves in, with trunks under the surface, send up tiny branches with two or three leaves and a few minute flowers. In more favorable conditions large areas are covered with shrubs of the heath family, notably the Labrador tea and huckleberry as well as the heath-like crowberry.

There are no plant families that are distinctly arctic. All the species belong to families whose centers of distribution are farther south. Large deposits of coal in lands now covered with ice and snow, however, indicate that at some distant day the climate must have been very much warmer.

In milder regions mountain tops of sufficient elevation provide conditions for growth somewhat like those that prevail in the arctic lowlands and when the mountain ranges extend roughly north and south they may provide a highway over which northern plants can spread far toward the equator. In many cases the identical species that grow beyond the arctic circle may thus reach nearly or quite to the Mexican boundary. Although comparable to arctic regions as regards temperature, there are various other features of elevated regions that combine to make conditions quite different from those near the poles, and this has resulted in a number of forms that resemble northern forms but are better classed as alpine than arctic. Contrasted with arctic regions the mountain tops have a regular succession of day and night and a greater amount of light during the day. Owing to the elevation there is greatly reduced air pressure and less carbon dioxide as well as a marked change of temperature daily. The rainfall is often scanty and the absence of clouds allows a greater amount of ultra-violet light to penetrate to the earth. In spite of these differences, however, the mountain summits have much the same general features as the arctic regions. At the highest points are found mosses and lichens similar to those of the tundra and below them are the grasses, cushion-plants and bloom-mats which form the mountain meadows. Still lower come the dwarf shrubs and stunted trees known as the elfin wood close to what is called the "timber line." Near the upper limits of tree growth the vegetation consists of needle-leaved evergreen trees but lower down deciduous broad-leaved trees are found and, if in the tropics, these may merge into the broad-leaved evergreens of the rain forest. Recalling the vegetation of the earth as a whole we discover that it has many indications of zoning that suggest those of the mountains. The principal difference is that a thousand miles in latitude corresponds to a few thousand feet in altitude. Beginning with the broad-leaved forest at the equator we pass through a zone of deciduous forest to a needle-leaved evergreen belt from which we emerge into a grassland that vanishes far northward in the arctic tundra.

Work for the Month in the Garden

SAMUEL GOLDING

WITH the opening days of Spring, much work confronts the gardener on every side. Make another successional sowing of peas, which should be followed at intervals of about two weeks. Sow the main crop of onions and parsnips, salsify, some turnips, Swiss chard, more spinach and lettuce, kohlrabi, celery, cabbage, etc. Plant out from frames after they have been thoroughly hardened. All brassicas, lettuce and onions which were sown early inside may be planted into their final quarters. Some care is necessary when carrying out this operation to prevent unnecessary injury to the roots. Use a long trowel to get the roots down as far as possible, and make the soil around them quite firm. Plant out early leeks in well manured trenches. They are gross feeders, and will repay generous treatment. Some of the earliest celery can be planted out, but do not force or unduly hurry these plants as sometimes the very early sown is prone to bolt or run to seed.

Plant early potatoes. It is always advisable to change the ground for this important crop, and new seed is also an important factor in securing good yields of the tuber.

Tomatoes, egg plant, peppers and other tender vegetable plants that are growing on in the frames, should be allowed plenty of room to develop. Keep them near the glass to encourage and maintain a sturdy growth.

Give abundance of water to crops growing under glass and pay attention to proper ventilation, as the more tender seedlings are very susceptible to the sudden changes of temperature which oftentimes occur at this season. Continue to cover the sash at night until danger of frost is past.

Lose no time in finishing up new work on lawns. Grass seed sown during this month quickly germinates, and if the weather is favorable, will be well established before the hot days are here.

Any alterations, dividing and transplanting to be done in the perennial borders should be taken in hand now. This alludes to the late Summer and Fall blooming subjects. It is good practice to divide and transplant Spring blooming plants during September so that they will become established before Winter comes. Cuttings of perennials will root freely now, and the plants will bloom well later on. They are most useful for filling any vacant spaces in the borders.

The herbaceous plants are gross feeders and appreciate generous treatment. Fork in a good mulch of good farm manure.

Plant out all biennials that have wintered in the cold frames.

Prune outdoor roses; hybrid perpetuals require a more severe pruning than the teas and hybrid teas. These may have all weak and useless wood removed and should be cut back to a good eye. Plant new beds as early as possible, and prepare their quarters very deep and dig in plenty of good cow manure, making them firm after planting, and cutting them well back.

Continue to plant deciduous trees and shrubs, fruit trees, and evergreens. Cut off any damaged root with a sharp knife and cut the head well back after planting to maintain a balance between the roots and tops. See that they do not suffer from drought until they are established, that is, when root action is active once more.

Sow outside for late blooming, a full line of annuals: poppy, Eschscholtzia, mignonette and other kinds, which are known to resent transplanting. These should be sown where they are to bloom and thinned when they are large enough to handle, allowing enough space for the proper development of each plant.

Look over the stock of dahlia tubers and start those which are needed for propagation. When dividing the old clumps always be certain that the selected tuber has at least one eye. One can always be sure of this if the roots are started into growth before making the division.

Cannas should be started at once. They quickly respond to a little heat. Many of the new varieties are real acquisitions to the garden.

MAY

This is one of the most important months on the calendar, from the gardener's point of view, and demands for his immediate attention will be in evidence in all departments of the garden.

A full line of vegetables can be sown during the month. The earliest plants and seedlings will now be growing apace, and every effort must be made from now on to sow the seed at proper intervals to maintain that perfect succession so desirable throughout the growing season.

Stake early peas as soon as they are well above the ground. This prevents any from trailing on the soil and becoming matted by growing together, and staking is also a protection from the cold and cutting winds which often prevail during the early days of the month.

Plant all potatoes at this time.

Prepare the hills for melons, squash and cucumbers. These hills may be made about six to eight feet apart, according to the space at planter's disposal. Mix some good manure with the soil.

Lima bean poles can be placed in position. These are usually placed about four feet apart each way, and if done now will be all ready for planting with the advent of warm weather.

Sow some celery seed in the open ground for late work and also more string beans. Early sweet corn, bush lima beans and okra may be sown if climatic conditions permit. Early tomatoes may be planted out in a sheltered place, but one must use some judgment as to when to plant, as the locality and position of the particular garden has a great influence on the time of planting. It is best to be cautious regarding very early outside planting, if one should have ample facilities for protecting the plants. At this time the frame room is generally taxed to its fullest capacity, as the more tender bedding stock needs protection.

Give attention to the edging of garden paths and drives and have a good supply of stakes on hand to meet the demand which will soon be made upon them for use in the flower garden.

A friend of mine who ought to know better has many unhappy days because he hasn't sense enough to lose himself in thinking about the problems of other people. He hasn't learned the scientific truth of the statement "He that loseth his life shall find it." If you want happiness get it by forgetting about yourself in being useful to others. FORMS.

The Greenhouse, Month to Month

GEORGE F. STEWART

THE month of April is one of the busiest months of the whole year in the greenhouse, a great deal of time being used in transferring many plants, that are to be planted outdoors, to cold frames for hardening off. It is so easy to forget details, which, if neglected, will prove detrimental to fruits and plants later on. The greenhouse man should work out a daily system, as far as possible, so that daily duties may be done at certain stated periods of each day. System is a great time saver, especially when, as at the present time on account of business depression in so many lines, many places are short handed.

This month the cool greenhouse hard wood plants that have been used during March for house decoration and flower show purposes should be repotted, if they are heavily rooted in their receptacles. Some of the lighter rooting species will go a second year with a light top dressing and weekly applications of Clay's Fertilizer, while they are making their growth. I would include under this heading such plants as acacias, *Bauera*, *cornelia*, *chorizema*, *eristemon*, heaths, and other Spring flowering hardwood plants, known by many as "New Holland hardwood plants." A good compost for potting these plants is upland loam, for the stronger rooting sorts, with about a third of good sharp sand added. To those that have more delicate roots give equal parts of loam and peat, adding the same amount of sand, with some fine charcoal. Pot firmly and do not over-pot. Personally I never give a hardwood plant more than an inch of shift, unless it is a very coarse rooter. It shows culture to have a large plant in a small receptacle. Defer pruning, and shaping the plants until they have begun to root into the new compost. I think that they break more evenly and heal over the cuts more quickly.

Cool bulbous plants should be watched carefully to have a succession when required. We are now likely to have occasional hot days, forcing them a little faster than last month. They can be held for a long time after beginning to show color in a cool frost proof pit with a cement floor.

Specimen fuchsias and geraniums should now be growing vigorously in their flowering pots. Stimulate occasionally with fertilizer and manure water. Water at least three times with clean water between applications. Pinch the points out of the fuchsias to keep them in shape, especially on the strong growths. Allow eight weeks from the last stopping to the date they are wanted in flower. Geraniums break naturally, if the flower buds are picked off. The same length of time as stated above is required to bring them into full flower after the removal of flower buds. These notes also apply to fuchsia baskets, and ivy-leaved pelargoniums that are used for hanging in any position for decorative effect.

Single stem chrysanthemums, if large blooms are required, must be attended to, moving them along to their flowering pots as quickly as possible. Bush plants, as regards potting, should be treated as above. There must be careful stopping to keep them symmetrical, cutting any shoot that is taking the lead faster than the others.

Towards the end of April sow seeds of "herbaceous calceolaria," if one desires large specimens the following year for exhibition. One can have a nice sturdy little

plant before the hot months of Summer. It stands heat much better than those of later sowings, and when the cool Fall nights arrive, if given the proper compost, will grow like a weed.

Chinese primroses, *Primula stellata*, *Kewensis*, *Obconica*, should be sown this month, but *malacoides* will be better left until later.

Do not forget the young carnations and roses intended for benching by the end of June. Better success with the carnations, I think, can be had by pot growing until planted out on the benches. From observation and practice, the plants are more easily controlled than when planted out in the field. Insect pests may be never seen if reasonable precautions are taken, and finer and better stemmed flowers may be had when the short day arrives. Nice plants in four-inch pots are about right to plant in the carnation and rose house, about the above-mentioned period. Move them along with that end in view in a nice, airy temperature, avoiding draughts by careful ventilation.

Tropical plants such as Allamandas, *Ixora*, *clerodendron*, *cucharis*, anthuriums, flowering and foliage varieties, crotons, marantas, etc., are now growing vigorously. Allow each specimen plenty of space as it is then much easier to combat insects than when overcrowded on the benches. In my experience, over-crowding of plants in a humid atmosphere is ideal for the breeding of red spider. Syringe freely on all bright days; admit air freely on all days when the temperature allows it. I do not believe in the sweat box idea for these plants, as experience has proved that they will grow as well in a lower temperature than was practised in our earlier days of gardening. To keep insects in check during the rest of the season I have found that a thorough spraying with Imperial Soap Spray, according to directions, adding a wine glass of kerosene to every three gallons of the water-diluted mixture, kept well agitated during the application every two weeks, is effective. There will then be very little trouble with the usual breeds of insects. Choose a cloudy day for the operation, and even during the hot months, have a little heat in the pipes.

The early fruit houses will soon be ripening their fruit. Never syringe after the fruit begins to show color. Keep the houses good and airy. Nectarines, in my opinion, are better for forcing than peaches, as they are not so commonly grown out doors, and many people prefer the flavor of this fruit. Keep a sharp lookout for any unnecessary shoot that will not be required for next year's fruiting on any of the trees. Do not overcrowd the trellis.

Grape vines will now all be starting into growth. Disbudding must be strictly attended to. Several buds are always to be found at the end of the spur. Select the bud nearest the rod if it is stronger. Never be in a hurry to tie the shoots down to the wires as a jar of a door will often snap the shoot. One grower, I knew, maintains that nearly every grape house he has seen is wired too near the glass. His idea is that each shoot should have plenty of head room to develop until the weight of the bunch naturally brings it down to the desired position. Modern wide glass structures certainly need more air

space between the glass and the leaves than is generally seen. Scorched leaves are too commonly observed in these modern grape houses. Pinch the shoots two joints ahead of the bunch and every lateral one leaf from the shoot. Give the late grapes plenty of top air, and let the temperature rise naturally with the season. On warm days ripening fruit will take top and bottom ventilation to develop the bloom. Avoid extreme in temperature as much as possible.

Melons may be had in succession if one has ample room and time at his command; also strawberries brought in in batches every two weeks until such time as they may be had out doors. These notes are simply reminders. Every one should have an up-to-date American book on fruit culture for indoors; also another on vegetable forcing, as every year more and more demand is made for fruit and vegetables the year round.

Pot any of the Spring flowering orchids which may require it, just before the next year's growth begins to break. However, always remember that the less an orchid of the evergreen type is disturbed, the better it will thrive, providing the compost is fresh. Avoid extremely high temperature, even for *phalenopsis*, for it can be grown in a much more airy house than was believed possible in years gone by. *Cattleya Schroderae* I have grown in a carnation house up between the ridge ventilators where at night it was often 45°, very successfully for years, never changing its position Summer or Winter. Much depends on watering; and high temperature has more to do with the deterioration of these plants than anything else, especially during the Winter months. *Odontoglossums* are now flowering, and it is a pity that this most beautiful orchid dislikes our hot Summer so much. Heavily shaded with blinds raised from the glass to allow air to circulate freely, and with water running over the glass from the ridge down on all hot days, is the most successful method so far. This should be accompanied by plenty of ventilation, top and bottom. Wage a continued warfare on all insect pests on orchid plants at all times.

Love your plants. Read all you can about them, especially how they are found growing naturally. Visit your neighboring gardeners in a friendly way to compare experiences. Confess how little we really know about plants, after all our experience. Confession of ignorance is good for gardening as well as for the soul.

THE FRUIT GARDEN

(Continued from page 120)

LET YOUR TASTE BE YOUR PLANTING GUIDE

Now it is not supposed that everyone who makes an attempt at fruit gardening, either purely for pleasure or as a source of fresh fruit for the home, should try to grow all of these kinds or even a half of them. Everyone has a particular liking for some one or more of these fruits, so let this be your planting guide. Select a good rich plot of well drained soil. Then secure all the available information on these fruits and apply it accordingly. I am sure that the interest and enthusiasm that a "good start" creates will help you to overcome any problems in the care of them that may develop later.

CAREFUL ATTENTION MUST BE GIVEN

The fruit crop will not produce itself more than any other kind of a crop. In fact, I believe the fruits will respond to a little extra care more readily than others. They must receive careful cultivation, training, fertilizing and spraying when necessary. The true gardener does all these almost by instinct, while the amateur soon learns

them by actual experience. An old apple tree, standing unproductive for years, with a little proper fertilizing, etc., will usually produce a surprising amount of fruit in a couple of years. As stated before one can expect to encounter a few difficult problems, a troublesome insect or disease may cause havoc, or the vines or trees may not grow as you expected and many other things, for all of which there is a cause. It is the finding and the conquering of these that lends interest to the game, and finally, when the splendid crop is matured, it is this feeling of victory over adversities that produces an added sense of joy and satisfaction.

EVERY HOME SHOULD HAVE ITS FRUIT GARDEN

I have always maintained that where space permits every home should have its fruit as well as its vegetable garden. If we have the luscious fruit right at our own doors we are going to eat plenty of it and enjoy it very much more than the half-par products of the market. We are going to can, preserve and make jellies and jams out of the surplus and thus reap the benefits throughout the year. Where the hand labor is available dwarf trees may be used and the other fruits so arranged as to give a fine formal scheme. The floral effect at blooming time, followed by the conspicuously colored fruits, could furnish nothing more pleasing or effective in the planting arrangement.

MAKE THE GARDEN YOUR HOBBY

It is unfortunate that many people are confined indoors with their business duties most of the day. To keep in the best of health and vigor it is certainly necessary for them to spend an hour or more of each day in the open air and sunshine. Then, to furnish this outdoor recreation, a pleasant diversion, and lots of fresh fruit, why cannot they develop the fruit garden as a hobby and add both years and pleasure to their lives.

A MARECHAL NIEL ROSE STORY

(Continued from page 112)

paying crop. The writer had cut as high as five hundred at a cutting. The floor space was used for Calla lilies, which though a little taller from being shaded were nevertheless good.

When the fame of this rose productiveness got abroad a number of others undertook to grow the Marechal Niel the same way, but although they got a good surface covered with wood their crop of blooms never equaled ours. My idea always was that their being on their own roots they got the growth, etc., but the influence of the La Marque stock was what gave us the enormous quantity of blooms. I may be wrong in this, as location and treatment might have had some influence, as I have found similar action in other things.

CLOTHING THE GROUND BENEATH TREES

IN gardens where large trees are growing the ground beneath them is too often regarded as useless, and in the consequent neglect it is frequently allowed to become more or less an eyesore. It is certainly not always easy to beautify these shady spots, especially in the case of ground beneath old Yew-trees, or similar subjects where the numerous roots occupy the whole of the surface-soil. But with proper treatment, accompanied by the necessary patience, even these unpromising places may, to a certain extent, be beautified by a suitable selection of plants. The first steps to be taken are to fork over the ground, and where the mat roots are particularly abundant put a layer of soil. To this may be added some decomposed manure or leaf-mold. Any old discarded soil from the potting-shed or elsewhere will serve the purpose quite well. It should, of course, be remembered that the innumerable tree roots are always greedily absorbing nourishment from the freshly-added compost, so that it is advisable to renew the top-dressing every twelve months, or even oftener if the occasion shall demand it.

The Butcher's Broom, when once established, is an excellent dwarf shrub for growing in hungry soils. It will stand the drip well, it does not object to shade, and it will flourish exceedingly well in time of drought. Ivy, of course, makes an ideal evergreen clothing for ground under trees, neither is it at all difficult to establish. The gold and silver variegated forms of *Euonymus radicans* may also be relied upon for the purpose under consideration. They are beautiful trailing plants, and look most attractive at any season of the year. Then there is the handsome *Berberis (Mahonia) aquifolium*. It is worth while taking special care in planting this shrub. Give it a good rooting medium to start with, and water it well in. Afterwards it will take care of itself and well repay any pains taken with it. Whether in the Spring, when the bright golden blossoms are showily asserting themselves, or in the Autumn and Winter during the period of rich leaf-coloration, this charming plant always has some special attraction. Periwinkles and St. John's Worts, too, may be freely employed to beautify the ground beneath trees, and they will both flourish in the poorest of soils without any sunshine.

Among bulbous subjects there are a few which will give a good account of themselves in the position indicated. Snowdrops and Scillas, Ornithogalums, and *Eranthis hyemalis* will all do well under trees. Special mention might be made of the lovely hardy Cyclamens. These are easily established even among the active roots of trees, and they luxuriate abundantly in the shade which the branches afford. The foliage of these little woodland gems is quite effective, while the dainty flowers last for a considerable time. The tubers should be put in just below the soil surface. These, together with the other bulbs mentioned, should be planted in bold, irregular groups, and they will multiply and spread in their own fashion and duly gladden the earth with their gay blossoms. Then, of course, there are Primroses and Polyanthus, while even Foxgloves may be coaxed into bloom in certain localities.

This list is not by any means a complete one, but a careful planting of those sorts mentioned will, at any rate, do much towards beautifying those spots which neglect has previously allowed to remain bare and unsightly.—*Gardening Illustrated*.

PLANTS THAT ARE PESTS

IT must, I suppose, be admitted that a plant which behaves as a pest in one soil or climate may be quite orderly and charming in another; also that a plant which is a nuisance in the rock garden may be a most desirable subject somewhere else. That being so, there must inevitably exist a number of opinions as to the moral character of various plants whose reputations have at one time or another been called in question. Notwithstanding, it is always permissible to make observations on subjects of which one personally has had painful experience; this so that those who are planting may at least take due warning.

One of the earliest of my errors in this respect was the chance planting of a root or two of the Welsh Poppy (*Meconopsis cambrica*) in some steps. This pretty thing, so admirable for woodland, has not yet been extirpated, and I doubt if it ever will, so firmly is it entrenched in the masonry, so grimly holding ground that might be occupied by something better. I am assured, however, that the beautiful bronze (single) form does not offend like the type.

Oxalis spectabilis (?), lovely in flower and foliage is even a worse pest than the Poppy, *i. e.*, in the wrong place. It spreads by underground runners, probably by seed and by begetting legions of little bulbs which, on lifting a plant, scatter all over the place and are small enough to be carried on one's boots and tools from place to place. *Oxalis spectabilis*, once you get it in a soil that it likes, is a very murrain, and on the knees of repentance have I besought it these many years to take its spawn elsewhere.

As for the creeping Linarias, I have yet to meet the one I can contemplate without distrust. *L. cymbalaria* (Kenilworth Ivy) has never had much opportunity of doing its worst here. The admirable *pallida* was put in a few years ago on the assumption that it was not a rampant colonizer, but it, alas! is also branded with the same family curse. Even pretty little *hepaticifolia* is displaying symptoms of energy which arouse suspicion, and I am not unduly fidgety in regard to these things.

Helxine Solieroli will swarm over anything with the rapidity of a fungus, but one can here rejoice in its wonderful glossy green and flowers like gold dust, knowing that a sharp frost or two will clip its wings and bring it back to moderation before another Spring. Not so *Epilobium nummularifolium*, which, though hardly so difficult to weed out, is too lively and prolific for the rock garden. Nor can I suffer gladly another of its genus, called, I think, *E. glabellum*, despite its more attractive appearance. But, whereas these only creep on the surface and sow the parish with their feathered seed, what shall one say of *Convolvulus althaeoides* (properly *C. tenuissimus*) of most catalogs? No more beautiful plant lives than this one, with its big rose-satin trumpets and finely cut, pale gray foliage. (The true leaves are green and almost exactly like those of a young Ragwort.) Yet it is the most rampaging, fighting, overwhelming weed that ever burrowed into forbidden ground. The couch-like roots know no obstacle, recognize no limitation. They will push under a gravel path or flight of steps without showing a sign until, 4 ft. or 5 ft. away, you will one day observe a little rosette of green, crinkly leaves and realize in sackcloth and ashes that *C. althaeoides* has not only "got there," but fully secured his lines of communication. Still, one cannot be too severe on a plant so lovely and one so generous with its flowers.

Oxalis corniculata rubra, I am ready to believe, may be a pleasing object where one can afford to let it have its own way, but I know nothing so difficult to get out once it is established, nothing that spreads so rampantly. It has no compensations to offer me in return for the depths of woe into which I have been cast by its unwelcome persistence. The exquisitely beautiful *Cardamine pratensis fl.-pl.* can be troublesome too, in some places, for, in forfeiting the usual means of procreation by adopting the double form, it has ingeniously devised another means of increase, *i. e.*, by layering its leaves. Thus, every lower leaf that rests on moist soil sends down a tiny rootlet from its midrib and a new plant is born. This youngster immediately follows suit, with the result that a single plant of *C. pratensis* will soon swarm over a square yard. But, again, one cannot be too hard on a plant so attractive, and its surplus offspring are easily uprooted.

Some of the *Cotulas*, *squalida* to wit, will give trouble if allowed too much license, and *Acæna Nova Zealandia* is not only too boisterous for a rock garden of moderate size, but its burrs are an intolerable nuisance. For these reasons the latter has been banished, and the old Red Valerian (*Centranthus rubra*) has also had to go, even the one clump which for long was spared and suffered for the sake of the butterflies. With *Crucianella stylosa* one must also be careful, for it is often much too vigorous for the rock garden and a plant that cannot be dislodged without removing the stones which it enmeshes.

The old St. John's Wort (*Hypericum calycinum*) would hardly be planted in the rock garden by the simplest of tyros, but as there are doubtless some who may be tempted to put it in as a carpeting for shrubs, I can advise them to make sure that it is kept at a safe distance. An average path, for example, will not keep this pushful plant within bounds, nor will a stone wall. Its hydra-headed root-stems are more difficult to stop than those of any other plant with which I am acquainted, the wild white *Convolvulus* not excepted, and for having given it too much quarter in the past we are being punished by *H. calycinum* no less indignantly than the indiscreet deserve.—*The Garden*.

To read without reflecting is like eating without digesting.—*Edmund Burke*.

FRAGRANT ROSES

WERE one asked to name the most striking characteristic of the newer Roses, the answer must be in one word—"color." Since M. Pernet-Ducher introduced Madame Edouard Herriot (the so-called *Daily Mail* Rose) in 1912, Rose lovers have enjoyed a wonderful period of progress in this respect. So much so that our French friends appear to have relegated form and everything else to the background in order to worship color exclusively. In our own countries the long-established English standard of form in flowers has saved us from this extreme; however one may admire, for example, the saw-edged flowers of the American carnation, it must be admitted that the smooth-petalled flower by the British florist has an unequalled charm and beauty. The maintenance of too close an adherence to any particular convention of the kind would, however, be a bar to progress. Twenty years ago no rose hybridiser would have dreamt of retaining the Padres, Red Letter Days, K. of Ks., Isobels or other semi-single or single-flowered roses found amongst his seedlings in the flowering season. Such are disappointing to those who cannot appreciate a rose which is not full, but what would our gardens be without the numerous modern "decorative" hybrid teas which flower almost without cessation from June till Autumn, producing a profusion of bloom quite unknown to nineteenth-century gardeners?

It would be interesting to hear what that great rosarian, the late Dean Hole, would say were he to pay a visit to one of our present-day National Rose Shows. But perhaps he is now gardening with roses beyond our ken in form and color and in fragrance. Ah! there's the sting, for too many of our new roses lack perfume, and in fancy one imagines the Dean sorrowful as he goes round the Show. But our rose raisers are keenly aware of the deficiency, and at no distant date there is little doubt that the ranks of sweet roses will be considerably strengthened. The sense of smell, nevertheless, appears to have been dealt out in somewhat unequal proportions, and the writer is afraid that raisers of new roses at times find in their own bantlings a fragrance, the detection of which is denied to ordinary mortals. In any case, it is difficult to obtain information of a fully satisfactory character as to scented varieties; even the list of fragrant roses given in the National Rose Society's handbook does not to the present writer appear to be infallible, and, as a guide to himself, and as a possible help to others, notes have been taken in successive recent Summers respecting the fragrance of some seven hundred varieties of hybrid roses.

Amongst the sweetest twenty-four hybrid roses should be placed Mrs. Bryce Allen, Hugh Dickson, General MacArthur, George Dickson, Crimson Emblem, Edgar M. Burnett, Hadley (one of the best of dark roses), H. E. Richardson, Madame Abel Chatenay, Madame Maurice de Luze, Mary Countess of Ilchester, Mrs. A. E. Coxhead, Lady Greenall, W. E. Lippiatt, Mrs. Maud Dawson, Zephyrine Drouhin, Duchess of Wellington, Ulrich Brunner, Mrs. Richard Draper, Commandant L. Barte, Alfred Colomb, Mrs. J. Laing, Beauty of Waltham, and the old favorite La France. Of these, Duchess of Wellington possesses so strong and sweet a tea fragrance as to resemble closely the scent of freesias; flowers of Lady Greenall will scent an entire room with delightful perfume, as also will Madame Abel Chatenay.* In degree of sweetness the above set of roses is closely followed in fragrance by Admiral Ward, Chas. J. Graham, Captain F. Bald, Chateau de Clos Vougeot, Cheerful, Colleen, Duchess of Westminster, Edward Mawley, Florence W. Veitch (one of our grandest crimson roses, whether as a climber or large bush), Gustav Grunnerwald, Gruss an Teplitz, Hoosier Beauty, Jonkeer J. L. Mock, Laurent Carle, Lieut. Chauré, Madame Meha, Sabatier, Molly Bligh (a fine, large new pink rose), Mrs. Forde, Mrs. Geo. Norwood, Ophelia (soon to be in every garden), Walter C. Clark; and, of course, quite an extensive list could be named of roses which possess tea perfume in varying degree.

It will be observed that most of our sweetest hybrid roses are of red or pink shades. Probably the sweetest white rose is the rugosa Blanc Double de Coubert, which reminds one that the large pink flowers of the hybrid rugosa Conrad F. Meyer are also powerfully sweet.—*Irish Gardener.*

* *Gardeners' Chronicle*, 1914, p. 126. Mrs. J. Laing would be classified as a tea rose.

AUTUMN CARE OF FRUIT TREES

I AM now firmly convinced of the value of Winter spraying as a preventative of fungous diseases. Last year there was little disease of any kind, and one could not be quite sure of the results of spraying. This year Apple scab and brown rot are prevalent, and spraying has a chance to show its value. The contrast between unsprayed and sprayed trees is so striking that I no longer need any doubt. It was the best crop of Apples and Plums in two orchards that were sprayed last Winter, and the foliage is much stronger and healthier. There are blocks of Worcester

Pearmain in four orchards. In one that was Winter-sprayed the crop is a picture, the fruit being well developed and practically free from scab. In the other orchards fruits of this variety are badly scabbed, and there is a large proportion of small fruit, in spite of Summer spraying with lime-sulphur. In Plums there is much less brown rot in the orchard that was winter-sprayed. This has given me such a lesson that I shall go in strongly for spraying next Winter, and shall rely on this entirely as a preventative of fungous diseases, concentrating on insect pests in the Summer. It would, of course, be foolish to deny that the normal summer spraying against fungous diseases does good; but it is often disappointing, and I doubt if it is worth while when winter spraying is so successful. The wash used during the past two winters was a combination of copper sulphate and caustic soda, but lime-sulphur will be substituted in the coming Winter. Caustic soda should not be used repeatedly, as it has a hardening effect on the bark. Moreover, it is so unpleasant for the men who have to apply it that a change will be welcome. Caustic soda was used only because the trees were rather heavily coated with moss, due to neglect of Winter spraying during the war. Lime-sulphur is an excellent cleanser if the trees are not too mossy.

Fruit-growing becomes more and more scientific. Hitherto the manuring of orchards has been done on more or less haphazard lines. Most growers restrict their manuring to Winter dressings, either at regular intervals or when the trees seem to need help. There is always an extra amount of manuring done after a heavy crop because it is recognized that the trees have undergone a strain and want feeding if they are to continue cropping. Those who have given the matter much thought, however, must have realized that manuring in the Winter is too late to help the yield of the following year, since the fruit buds are formed during the year previous to that in which they open. Moreover, they burst in Spring before the roots have started into action and become capable of utilizing the manure and feeding the tree. For the production of strong bloom and the setting of fruit the tree must, therefore, depend on assimilated plant food which it has been able to store during the previous season.

A special soluble organic manure is applied in early August. This time is chosen because the swelling and development of the crop are then nearing completion. The food material given will not, therefore, pass into the fruit. It will go instead into the leaves, where it will be fabricated; and, not being wanted for immediate needs, must be stored by the tree for the next year, both in its fruit-buds and its system generally. This August dressing is followed by Winter manuring with some lasting organic material, such as hoof or meat meal. This insures that the trees shall be able to support the blossoms by a vigorous growth, so that the fruit may be held and the work carried on. These two dressings are given annually, and it is considered important that there should be no break. As a result it is hoped that the distressing habit of alternate year bearing, common to many late varieties of Apples, has been overcome.

Although I have some trees in grass which have so far proved quite successful, I do not welcome the idea of extending the system, as it gives less scope for manuring and involves a lot of mowing. *The Gardeners' Chronicle* (British).

DEPARTMENT OF BOOK REVIEWS

AMERICAN ROSE SOCIETY

1922 *American Rose Annual* (American Rose Society). This book includes 192 pages of text plus 16 inserted sepia plates and two color plates, the frontispiece being a double-size plate of a rose not yet introduced. Inasmuch as the members of the society make the *American Rose Annual* by their contributions and experience, it closely reflects the growing rose spirit of America. In 1922, there are some outstanding features. Three articles on back yard rose gardens tell the story of success under unfavorable conditions. A symposium, participated in by all the important rose hybridizers of America, and by many amateurs, tries to answer the question "What New Roses Does America Need?" Responding to many requests, there is presented a most complete compendium of information concerning insects and diseases that bother roses, probably the best and most useful information of the sort ever provided in America. Reports of the society's Test Gardens, observations concerning roses abroad, an accurate list of all the new roses of all the world, an intelligent account of the new English roses by the secretary of the National Rose Society of England, and a thoughtful survey of the rose cut flower situation, carry on the breadth of the book. There are as well many interesting rose notes provided by members of the society and a dozen and more additional articles, all original and forceful. The life and work of America's greatest rosarian and plant hybridizer, Dr. Walter Van Fleet, are presented in a symposium of appreciation. (Continued on page 128)

National Association of Gardeners

Office: 286 FIFTH AVE., NEW YORK

President—Robert Cameron, Ipswich, Mass.

Vice-President—John Barnet, Sewickley, Pa.

Secretary—M. C. Ebel, 286 Fifth Ave., New York.

Treasurer—Montague Free, Brooklyn, N. Y.

TRUSTEES (For 1921)—William H. Waite, Arthur Smith, D. L. Mackintosh, New Jersey; W. N. Craig, Massachusetts; H. E. Downer, New York.

DIRECTORS (To serve until 1923)—Alexander Michie, Long Island; George F. Stewart, Massachusetts; Theodore Wirth, Minnesota; George W. Hess, District of Columbia; Daniel J. Coughlin, New York; John Barnet, Pennsylvania; Montague Free, New York. (To serve until 1924)—William Gray, Rhode Island; William Hertrick, California; Albin Martini, Iowa; Thos. Hatton, Connecticut; Robert Weeks, Ohio; W. H. Griffiths, Michigan; Thos. W. Head, New Jersey. (To serve until 1925)—George Wilson, Illinois; James Stuart, New York; William Kleinheinz, Pennsylvania; John F. Huss, Connecticut; Edwin Jenkins, Massachusetts; Carl N. Fohn, Colorado; Joseph Tausen, New York.

SUSTAINING MEMBERS

New York—Mrs. J. J. Albright, George F. Baker, Edwin S. Bayer, Henri Bendel, Albert Clayburgh, W. R. Coe, Mrs. F. A. Constable, Paul D. Cravath, Mrs. W. Bayard Cutting, Mrs. Charles Daniels, Cleveland H. Dodge, Mrs. David Dows, Frank J. Dupignac, Mrs. Coleman du Pont, Childs Frick, W. H. Gratwick, Daniel Guggenheim, Mrs. W. D. Guthrie, Mrs. B. A. Haggin, Mrs. William P. Hamilton, Mrs. John Henry Hammond, T. A. Havemeyer, Mrs. L. A. Herman, Anton G. Hodenpyl, B. H. Howell, C. O. Iselin, Otto H. Kahn, Mrs. Frank B. Keech, W. Eugene Kimball, L. C. Ledyard, Jr., Adolph Lewisohn, John Magee, Mrs. Julius McVicker, Morton H. Meinhard, Mrs. Eugene Meyer, Jr., J. Pierpont Morgan, Mrs. J. Pierpont Morgan, Stanley G. Mortimer, Mrs. Harold I. Pratt, John T. Pratt, E. F. Price, Mrs. William A. Read, H. D. Roosen, Charles A. Sherman, Mrs. Samuel Sloan, Benjamin Stern, Mrs. W. Stursberg, Daniel Tatum, Mrs. R. M. Thompson, Mrs. Edwin Thorne, Mrs. Henry M. Tilford, Carl Tucker, Samuel Untermeyer, Mrs. Harold T. White, Mrs. Payne Whitney, E. L. Young. *New Jersey*—A. Albright, Jr., Charles Bradley, Joseph P. Day, James B. Duke, Mrs. Lewis L. Dunham, Mrs. Frederick Frelinghuysen, Mrs. K. S. Goodrich, Mrs. Gustav E. Kissel, C. Lewis, Mrs. Paul Moore, Hubert T. Parson, Mrs. Manuel Rionda, Leland H. Ross, P. S. Straus, Mrs. John I. Waterbury, Mrs. Ridley Watts, Sanders Wertheim. *Pennsylvania*—Samuel T. Bodine, Gen. Richard Coulter, Mrs. J. D. Lyon, R. B. Mellen, Gifford Pinchot, George F. Tyler, Edward A. Woods. *Delaware*—Irene du Pont, Pierre S. du Pont, Harry G. Haskell. *Connecticut*—E. Dinan Bird, Dr. Tracy Farnam, Mrs. Tracy Farnam, George M. Hendee, Miss A. B. Jennings, H. F. Schwarz, W. H. Truesdale, Edward L. Wemple, William Ziegler, Jr. *Rhode Island*—Gov. R. Livingston Beekman. *Massachusetts*—Miss M. R. Case, Mrs. William C. Conant, George P. Dike, Mrs. Henry C. Frick, Mrs. Louis Frothingham, Henry S. Hunnewell, E. K. Lawrie, Mrs. C. G. Rice, Prof. C. S. Sargent, Mrs. J. A. Spoor, Mrs. Bayard Thayer. *New Hampshire*—F. G. Webster. *Ohio*—F. F. Drury, H. S. Firestone, Mrs. Francis F. Prentiss, John L. Severance, H. S. Sherman, H. L. Thompson. *Michigan*—J. B. Schlotmann, E. D. Speck. *Indiana*—Theodore F. Thicme. *Illinois*—A. Watson Armour, Harry B. Glow, A. B. Dick, Clayton Mark, Mrs. Julius Rosenwald, Mrs. F. W. Upham. *Minnesota*—Mrs. Chester A. Congdon, F. H. Stoltze. *Iowa*—Mrs. G. B. Douglas. *Missouri*—August A. Busch, Dr. George T. Moore. *Virginia*—Miss Grace E. Arents. *West Virginia*—Mrs. Arthur Lee. *Georgia*—E. H. Inman. *South Carolina*—Robert S. Mebane.

LOCAL BRANCHES

Newport, R. I.: Andrew L. Dorward, chairman; Frederic Carter, secretary.

St. Louis, Mo.: George H. Pring, chairman; Hugo M. Schaff, secretary.

Nassau County, L. I.: John T. Everett, Glen Cove, chairman; John McCulloch, Oyster Bay, L. I., secretary.

Boston, Mass.: Robert Cameron, chairman.

SUSTAINING MEMBERS

Leland H. Ross, Madison, N. J. (William Lund, gardener); Edward L. Wemple, Greenwich, Conn. (M. C. Redlich, gardener); Henri Bendel, Great Neck, L. I. (Carl Peterson, gardener); Mrs. B. A. Haggin, Tannersville, N. Y. (James Warr, gardener) have become sustaining members of the association.

NEW MEMBERS

The following new members have recently been added to the membership of the association: H. D. Prosser, Islip, L. I.; A. Bulpitt, Port Washington, L. I.; Alexander D. Elder, Oyster Bay, L. I.; William Thomas, Great Neck, L. I.; Steve Dombrowsky, Locust Valley, L. I.

N. A. G. BOSTON BRANCH

A meeting of this recently organized branch was held at Horticulture Hall, Boston, on the afternoon of the second day of the Spring Flower Show of the Massachusetts Horticultural Society. About fifty members were present when the chairman, Robert Cameron, called the meeting to order. W. N. Craig was appointed

secretary. Members were present from New Bedford, Haverhill, Manchester, Willsley, Framingham, Natick, Newton, and other points; also from Newport, R. I. The coming Boston convention was discussed, and unless some important events necessitate a change, September 12, 13, 14, 15 will be the dates; the first two for business, the last two for sight-seeing. A set of by-laws for the use of local branches was submitted and discussed to be taken up further at the next meeting, and amendments to the by-laws relative to the reserve fund of the society and other matters pertaining to the finances of the society, as well as the Service Bureau and its value to members, and the proposed course for professional gardeners at the Massachusetts Agricultural College, Amherst, Mass. The meeting lasted over two hours and was interesting throughout. The next meeting will be held about the last of April, while several members of the association will attend and speak before the North Shore Horticultural Society, Manchester, Mass., and endeavor to secure new members there, and perhaps institute a branch of the N. A. G.

W. N. CRAIG, Secy. pro tem.

NATIONAL ASSOCIATION OF GARDENERS' BOOTH AT THE FLOWER SHOW

The booth at the International Flower Show this year again demonstrated the fact that it is a worth while source of bringing publicity to the association. Estate owners from all parts of the country called for information regarding problems arising on their places, and to discuss the possibility of engaging efficient men. A number of people called at the booth to inquire just what the association was, as they had vague and often incorrect ideas as to its aims and purposes. Satisfactory explanations were given to them by those in charge. Attractive pamphlets, setting forth the aims of the association were distributed in large quantities from the booth. These pamphlets can be had from the office of the association if any member desires to obtain some for distribution among his gardening friends in an endeavor to interest them to become members.

SIGN BOARDS

From one of the association's members located in St. Louis, the following interesting news items regarding the abolishment of sign boards along the Missouri highways, has been forwarded: "The State Highway Commission today adopted a resolution to enforce a provision of the new highway law, under which advertising matter cannot be posted along the state highways. All the numerous highway associations, automobile clubs and old trail associations, for the time being and until otherwise ordered by the commission, are authorized to remove all advertising matter on the right-of-way of the state highways and to substitute fingerboards showing the direction and distances to various cities. Later the commission will make some designations relative to imparting information to travelers on the highways regarding distances to cities, direction, etc., of a more permanent nature than it is anticipated the various associations will make. The prime object at this time is to get rid of the advertising matter now so generously displayed on trees, fence posts and billboards along the highways."

The attention of the Secretary's office was also called to a story which appeared in one of the New England newspapers, which tells of the stand taken by the Cape Cod Chamber of Commerce to rid the Cape of unsightly billboards and advertising signs which disfigure the highways. "The first step in this campaign was the preparation of a petition addressed to certain conspicuous advertisers and advertising companies using these billboards. This petition, which was very largely signed through the Cape, was based on a plea to protect the picturesque landscape of the Cape."

OPENINGS FOR APPRENTICES

In answer to the appeal made by the Secretary's office for opportunities for young men who are desirous of locating on private estates as apprentices, several superintendents and gardeners notified the Secretary that there were such opportunities on places of which they are in charge, and young men were sent out by the Secretary's office to fill these vacancies. The Secretary still knows of several desirable young men who would like to become apprentices on private estates, and if any member can provide for one or two young men, the Secretary will be glad to hear from him.

AMONG THE GARDENERS

Philip Bovington is now located at Redwood City, Calif., as head gardener to A. D. McBryde. Mr. Bovington was formerly head gardener on the A. R. Erskine estate, South Bend, Ind.

Edgar Osborne secured the position of gardener to John D. Horst, Sheerlund, Reading, Pa.

William Whelan, for many years gardener on the du Barry estate, Madison, N. J., and later to Leland H. Ross, present owner of the estate, has entered into business for himself at Johnson, N. Y. William Lund has succeeded Mr. Whelan as gardener to Mr. Ross.

Roy E. Mickelson, who was connected for several years with the Hibbing, Minnesota, Park Board, is now engaged in landscape work, serving the northern part of Minnesota.

Thomas H. Rogers accepted the position of gardener to Robert L. Bacon, Westbury, L. I.

Peter Stobie, formerly on the Charles de Rham estate, Cold Springs, N. Y., has accepted the position of gardener on the W. E. Kimball estate, Glen Cove, L. I., succeeding Jesse H. Framp-ton, who recently resigned.

John G. Walker accepted the position of gardener to H. E. Manville, Pleasantville, N. Y.

Thomas J. Roberts secured the position of gardener on the estate of Thomas Hunt, Tivoli, N. Y.

Herman Hoyer has accepted the position of gardener to Henry W. Sackett, Mamaroneck, N. Y.

James Warr, who just returned from a trip to England, has accepted the position of gardener to Mrs. B. A. Haggin, Tannersville, N. Y.

Ross Gault accepted the position of gardener to S. C. Pirie, Sea Cliff, L. I.

Donald MacGillivray accepted the position of gardener to J. K. White, Harrisburg, Pa.

Thomas Davies secured the position of gardener to James Bowen, Cold Spring Harbor, L. I.

The many friends of Donald McNaughton, superintendent of the E. S. Moore estate, Lake Forest, Ill., extend their deep sympathy to him in the loss of his wife on March 17.

NORTH SHORE, MASS., HORT. SOCIETY.

A regular meeting of this wide awake society was held in Horticultural Hall, Manchester, on the evening of April 5. Fully one hundred members and friends were in attendance. Prof. John S. Carver of the Essex County Agricultural School gave an interesting lecture on poultry which was followed with keen interest, the lecturer answering many questions at the close. Robert Cameron of Castle Hill Farm, Ipswich, President of the National Association of Gardeners, was present and addressed the meeting on the aims and principles of the organization, and referred to the coming Boston convention, September 12 to 15. He asked the co-operation of the North Shore gardeners to make the convention a great success.

W. N. Craig of Brookline followed Mr. Cameron and spoke at some length on what the N. A. G. stood for and asked those who were not members to join. George F. Stewart of Waltham, the third speaker, added his voice in support of the national association and said that it appealed to him more than any other organization he belonged to. P. C. Veinot, a charter member of the N. A. G. at Manchester, Alfred E. Parsons, and Eric H. Wetterlow, all commended the work being done for the gardening profession by the N. A. G. and pledged the whole hearted support of the North Shore Horticultural Society in helping to make the coming convention a pleasant and profitable one. Several present expressed a desire to become members.

Alfred E. Parsons exhibited a superb group of Nemesias in five and six-inch pots from seed sown August 10, 1921, and grown cool. The flowers were of remarkable size and the plants showed splendid culture. They were worthily awarded the society's silver medal.

INTERNATIONAL FLOWER SHOW

(Continued from page 119)

- Samuel Untermyer, Greystone, Yonkers, L. I.—*Pelia muscosa*. Honorary Merit. *Epiphyllum phyllanthoides*. Cultural Certificate.
 F. B. Duke, Cambridge Beach, Honorable Mention. *Odonotoda Vuystiana*. Gold Medal. *Odonotoda*. Royal Gony. Certificate of Merit.
 W. Alice Burpee & Co., Philadelphia. Sweet Pea on display. Silver Medal. Certificate of Merit to Milkmaid, white; Spokane, orange; Robin Hood, red. Grandstand, blue. (See also, note, Early Fern, cream pink.)
 Howard W. Allen, Richmond, N. J.—Red garden. Gold Medal.
 Andrew Wilson, Springfield, N. J.—Garden lawn sprinkler. Certificate of Merit.
 Stirling Postley, Oyster Bay, L. I.—*Phenix Roehelinii*. Certificate of Merit.
 Mrs. R. Mallory, Port Chester, L. I.—50 Carnation *Pocahontas*. Silver Medal.
 H. Schwarz, Central Park, L. I.—Seedling pink Carnation. Certificate of Merit.
 J. J. Blair, Tuxedo Park, N. Y.—Seedling red Carnation. Certificate of Merit.

Carnations, Commercial Growers

- 100 White.—1, Springfield Floral Co., Springfield, N. J.; 2, Le Cluse & Le Cluse.
 100 Light pink.—1, Le Cluse & Le Cluse; 2, Springfield Floral Co.
 100 Dark pink.—1, Springfield Floral Co.; 2, Harry O. May, Summit, N. J.
 100 red or scarlet, to cover all shades generally included in those colors.—1, Springfield Floral Co.; 2, Harry O. May.
 100 White variegated.—1, Scott Bros., Elmsford, N. Y.
 100 Yellow or yellow variegated.—1, Strout Inc., Biddeford, Me.
 100 Laddie.—1, P. J. Goddard, Framingham, Mass.; 2, Springfield Floral Co.
 50 Any new variety not in commerce—Silver Medal.—1, Wm. C. Haas, Livingston, N. J.
 Display of Carnations, covering 150 sq. ft. of space and containing not less than 1,000 nor more than 1,500 blooms. Decorative green of any kind, including plants, permitted. Quality of bloom, artistic arrangement and general effect to be considered in making award.—1, Springfield Floral Co.

Carnations, Private Growers

- 25 White.—1, Mrs. Arnold Schlaet (E. Lawrence, gdr.). Saugatuck, Conn.; 2, Mrs. F. K. Lewis (J. Smith, gdr.), Ridgefield, Conn.
 25 Light pink.—Mrs. Wm. D. Guthrie; 2, Mrs. Arnold Schlaet.
 25 Dark pink.—1, Mrs. Payne Whitney.
 25 Red or scarlet.—1, Mrs. L. L. Dunham, Madison, N. J.; 2, Mrs. Payne Whitney.
 25 Crimson.—1, Mrs. Robert Mallory (Wm. Smith, gdr.), Port Chester, N. Y.; 2, Mrs. Payne Whitney.
 25 White variegated.—1, Mrs. F. E. Lewis; 2, Jas. A. Macdonald (R. Hughes, gdr.), Flushing, L. I.
 25 Yellow or yellow variegated.—1, Mrs. Payne Whitney.
 25 Laddie.—1, George G. Mason (D. McGregor, gdr.), Tuxedo Park, N. Y.; 2, Mrs. F. A. Constable.
 Vase of Carnations, not to exceed 150 blooms. One or more varieties may be used. Decorative green of any kind, ribbon and any other accessories may be used, as long as Carnations are the predominant feature. It is intended to give the exhibitor the widest latitude in making this display. Vase to be supplied by the exhibitor. Quality of bloom, artistic arrangement and general effect to be considered in making award.—1, Jos. E. Widener (Wm. Kleinheinz, gdr.), Elkins Park, Pa.; 2, Mrs. F. E. Lewis; 3, Mrs. Wm. D. Guthrie.

Sweet Peas, Commercial Growers

- 100 Sprays bicolor.—1, Herman Mamitsch & Son, Tenafly, N. J.
 100 Sprays white.—1, Herman Mamitsch & Son; 2, John M. Barker, Morristown, N. J.
 100 Sprays red or crimson.—John M. Barker.
 100 Sprays light and lavender.—1, John M. Barker.
 100 Sprays pink or salmon.—1, Herman Mamitsch & Son; 2, E. P. Hostetter, Manheim, Pa.
 100 Sprays orange.—1, Herman Mamitsch & Son; 2, John M. Barker, Morristown, N. J.
 100 Sprays any other color.—1, John M. Barker.
 Display of Sweet Peas covering 100 sq. ft., arranged for effect.—1, W. Alice Burpee Co., Philadelphia, Pa.; 2, Herman Mamitsch & Son.

Sweet Peas, Private Growers

- Display of Sweet Peas, covering 25 sq. ft. Quality of bloom, artistic arrangement and general effect to be considered in making award.—1, Mrs. W. Redmond Cross (Anthony Sailer, gdr.), Morristown, N. J.; 2, Mrs. Wm. D. Guthrie; Stuyvesant Fish, Garrison-on-Hudson.
 Collection of six varieties, 25 sprays of each.—1, Mrs. F. E. Lewis; 2, Mrs. W. Redmond Cross.
 100 Sprays, one or more varieties, arranged for effect, greens permitted.—1, Mrs. Wm. D. Guthrie; 2, D. Guggenheim (T. A. Leyden, gdr.), Port Washington.

Dinner Table Decoration

- Sweet Peas exclusively. Other foliage than Sweet Peas may be used.—1, Mrs. Ridley Watts; 2, Mrs. W. Redmond Cross; 3, Mrs. Percy Chubb.

Cut Roses, Commercial Growers

- 100 Columbia.—1, L. B. Goldington; 2, A. N. Pierson, Inc.
 100 Any disseminated variety, white.—1, A. N. Pierson, Inc.; 2, Bedford Flower Co., Bedford Hills, N. Y.
 100 Ophelia.—1, A. N. Pierson, Inc.; 2, F. R. Pierson.
 100 Premier.—F. R. Pierson; 2, A. N. Pierson, Inc.
 100 Any red variety.—1, L. B. Goldington; 2, F. R. Pierson; 3, Briar-cliff Greenhouses (Silver Medal), Scarborough, N. Y.
 50 Crusader.—1, Duckham Pierson Co.; 2, Triandly & Schenck.
 50 Mrs. Aaron Ward.—1, A. N. Pierson, Inc.
 50 Sunburst.—1, W. W. Vert.
 50 Any other disseminated pink.—1, Bedford Flower Co., Bedford Hills, N. Y.; 2, Triandly & Schenck.
 50 Any other disseminated yellow.—1, F. R. Pierson.

BOOK REVIEW DEPARTMENT

(Continued from page 126)

Yankee Bird Namer and The Wild Flower Namer, by Horace Taylor. Doubleday, Page & Co., Garden City, N. Y.

These two little devices, each for identifying sixty specimens, are nicely contrived and easily manipulated in a way that should prove to be quite fascinating to children; but they might be serviceable to an older tyro also in entering fields in which no one ought to be a stranger.

In either set each of the four working cards contains upon its margins broad classifications into one of which the specimen in question can be placed without difficulty. After this first card has been properly turned and laid upon the foundation card with all of the sixty names it shows, through tiny windows, a limited number of names one of which must be correct. The superimposing upon this of a second classificatory card still further reduces the number of possibilities. The correct name is shown alone when the last of the four cards has been applied.

LOCAL SOCIETIES

WESTCHESTER AND FAIRFIELD HORT. SOCIETY

The monthly meeting of the above society was held in the American Legion Hall, Portchester, on Tuesday, March 14. Owing to the illness of the President the chair was taken by James Linane, the Vice-President. There was an unusual number of exhibits, and all were of good quality. 1st prize was won by Pres. J. Tough for 3 pots *Lilium formosum* for which a Cultural Certificate was also given; 2nd prize also received a Cultural Certificate, being a superb vase of carnation Laddie, shown by W. Smith; 3rd prize was also for carnation Laddie, and won by E. Beckett. Other exhibits included roses, mignonette, antirrhinums, violets and sweet peas. Five new members were elected and three applications were received.

The special committee appointed for the Flower Show to be held by this society and the local branches of the ladies' Garden Clubs of America, reported progress.

It was decided to hold the show in September and the proceeds to be divided between the Greenwich and Portchester Hospitals. Announcements will be made later from time to time as reports are received from the committee.

HARRY JONES, Cor. Secy.

THE CLEVELAND HORT. SOCIETY

The regular monthly meeting of this society was held on March 9, with Mr. Brydon in the chair. It was decided to hold a small exhibit among members the evening of March 30, with an entertainment combined. Ralph Huntington of Painesville, Ohio, was the speaker of the evening and conducted a questionnaire on gladioli, perennials, and annuals. Mr. Huntington was well able to answer all questions put to him. The members gained a good deal of knowledge as to new and rare varieties; also what was most suitable to grow in this section. A rising vote of thanks was given Mr. Huntington in which all the members present joined. R. P. Brydon exhibited a plant of Begonia Lorraine which was awarded a certificate of merit. Mr. Brydon explained how the plant had been in bloom at Christmas and had been exhibited then at the Florists' Club. He then pinched it back; grew it on; with the result that it was more floriferous than at its first blooming.

W. J. BRUCE, Secy.

THE AMERICAN IRIS SOCIETY

A meeting of the New York Exhibition Committee was held on March 15. Arrangements were made to hold the New York Iris Show in the Museum Building, New York Botanical Gardens, New York, on Saturday and Sunday, June 3 and 4, from 9 a. m. to 5 p. m.

The program for the Annual Meeting of the Society is as follows: Morning, June 3—Inspect Iris Show; 12:30 p. m. Luncheon at Mansion House. Afternoon, June 3—2 p. m. Annual Meeting, Reports of Officers and Committees, Election of Officers, Discussion; 3-7 p. m. Official Inspection of Iris Test Gardens.

The schedule for the Show is now being prepared and can be secured after April 15 from R. S. Sturtevant, Wellesley Farm, Mass., or Mrs. G. V. Nash, New York Botanical Gardens, Bronx Park, New York.

For the Committee,
 R. S. STURTEVANT, Secy.

ST. LOUIS ASSOCIATION OF GARDENERS

The Association met at the Forest Park Greenhouses on the evening of March the first. After the usual business session the evening was given over to an illustrated lecture on "The Building of Rock Gardens," delivered by Mr. D. Miller of the Missouri Botanical Garden. Mr. Miller related his experiences with rock gardens in England and the Eastern United States, and called attention to various methods of construction. These gardens were planted with various alpine plants, which of course will not stand the climatic conditions of the mid-western United States, and this fact led to a very interesting discussion about the plants suitable for planting in rock gardens in this section. It was finally concluded that a study of the native material of this or any other section of the country would yield sufficient subjects for the making of attractive rock gardens even in sections where alpine plants will not succeed. President Pring led the discussion and the writer as well as others took an active part. After the meeting the members were conducted to the show house of the Park by Messrs. Vitz and Stroble, to view a beautiful arrangement of Cinerarias.

Now—A Power Mower for Medium Sized Lawns

For years Ideal Power Lawn Mowers have been used for taking care of large lawns. The thousands of Ideal Mowers in use have definitely demonstrated their labor saving, money making qualifications.

However, there are thousands of lawns hardly large enough to warrant the purchase of a large power mower, yet with so much grass to cut that proper care becomes a big problem and an expensive problem.

It was for this vast number of medium sized lawns that the Ideal Junior Power Mower was designed. It is moderate in price, dependable, easy to handle, and costs little to operate.

The Ideal Junior is exactly the right machine for homes with lawns too large to conveniently care for with hand mowers for mowing the putting greens on golf courses and for parks and cemeteries as an auxiliary unit

for trimming up and cutting in close quarters.

For Larger Lawns the 30" Ideal Power Lawn Mower

For large estates, municipal parks, cemeteries, golf clubs, schools, colleges, etc., the well known 30" Ideal Power Lawn Mower has no equal. Does the work of 5 to 7 men with hand mowers. Costs about 50 cents a day to operate and soon pays for itself in labor saved.

Furnished with or without riding trailer.

For large parks, golf courses, etc., we build the Ideal Power Triple Mower.

Write today and get our large pictorial catalog.

A PRACTICAL HANDBOOK OF TREES, SHRUBS, VINES and HERBACEOUS PERENNIALS

By JOHN KIRKEGAARD

Formerly Assistant to Director of the Royal Botanical Gardens, Copenhagen, Denmark. Latterly Twenty Years in American Forestry and Botanical Work

Illustrations in Sepia. Planting Plans. 410 pages. 8vo. Beautifully bound in cloth. Price \$2.50 net. Mailing price \$2.71.

This practical reference book is the logical result of years of Practical work in the author's career. He has sought, and successfully, the simplest form of explanation and instruction in the message which he conveys from each plant and growing thing to the amateur or gardener who seeks to be tree-wise, shrub-wise and vine-wise. No book of recent years is so comprehensive and so practical as this volume. Exhaustive descriptions, variations from type and more technical matter must be sought in the Horticultural Encyclopedias, for in these pages the author stands as the interpreter of the plant to the planter. The character of information may be summed up in the sub-title of the book—THE HARDY AND ORNAMENTAL VARIETIES—THEIR CHARACTERISTICS: USES: and TREATMENT.

Adequate space is given to articles upon injurious insect pests, the adaptability of plants for certain purposes, planting, pruning, spraying and cultivation. In short, the author has endeavored to include whatever information the householder needs with which to secure the proper selection, care and treatment of such trees and plants as are best adapted for his purpose, then to aid him in properly caring for them.

286 FIFTH AVE.

NEW YORK, N. Y.

SPRAYING

is as

Essential as Fertilizing

Successful cultivation demands a knowledge of the habits of plant insects and diseases, and the proper remedies for their control.

APHINE, an effective remedy against all sap sucking insects infesting flowers, fruits and vegetables, is free of the disagreeable odors and features of most insecticides. It invigorates plant life and is unexcelled as a wash for decorative plants. Aphine will not injure the most tender flower or foliage.

FUNGINE is an excellent remedy for mildew, rust, and other blights. It is readily soluble in water and contains no sediment. Fungine does not stain the foliage but cleanses it.

VERMINE is a soil sterilizer and vermicide. It destroys cut, wire, eel and grub worms, maggots, root lice and ants, and will protect your gardens and lawns from ravages under the soil.

There is but one convincing way for you to become familiar with the merits of these products and that is to try them out for yourself. It will prove worth while.

Sold by dealers in various sizes.

More About the General Purpose Greenhouse for Private Places Institutions and Cemeteries

You might say it was stripped for the running. A house that has all the lastingness, all the lightness and all the growing advantages of our most expensive house, only that it is not so ornamental.

It lacks the grace and beauty of the curved eave, and the cornice effect that the moulded face gutter gives.

The construction of this General Purpose House makes it possible to cut down on the masonry cost without in any way affecting its staunchness and lastingness.

It's a clean cut practical purpose house, at a price most attractive.

We'll gladly write you fullest particulars, or why not get together and talk it over?"

HENRY A. DREER
714-716 Chestnut Street, PHILADELPHIA, PA.

“Do it right, or not at all”

The following letter was written by “Father John” Davey to the men in the Davey organization. It is reproduced here to give you an idea of the spirit behind these master Tree Surgeons

DEAR “BOYS”: “DO IT RIGHT, OR NOT AT ALL.” It was my father’s and has been my slogan for seventy-two years. Here is its history, as I know it: I was nearly four years old. My father was planting potatoes, in front of our neat little cottage, on a fine May evening.

I asked him if I could plant some. He opened up a trench at the end nearest the house. Then took a potato and said: “If I let you plant it will you do it RIGHT?” “I will do what you tell me.” Then, looking at me tenderly, he said, with a firm voice: “YOU MUST DO IT RIGHT, or NOT AT ALL.” He then went into the house and brought out a big iron spoon, and remarked: “Here is your shovel; keep it clean.” He then cut the potato in two, and made a mark for each piece, telling me I must put the *cut side* down, and went on to his work. I carefully laid the two halves in place, then took my *shovel* and looked at (what appeared to me) a *big ditch* that I had to fill.

Well, by sundown I had this huge hole filled, and father showed me where I could improve on the level, or grade. After saying my little prayers I retired, but father’s voice was heard: “Do it RIGHT, or not at all.” In the morning I awoke, and still that voice was ringing, “Do it RIGHT, or not at all.”

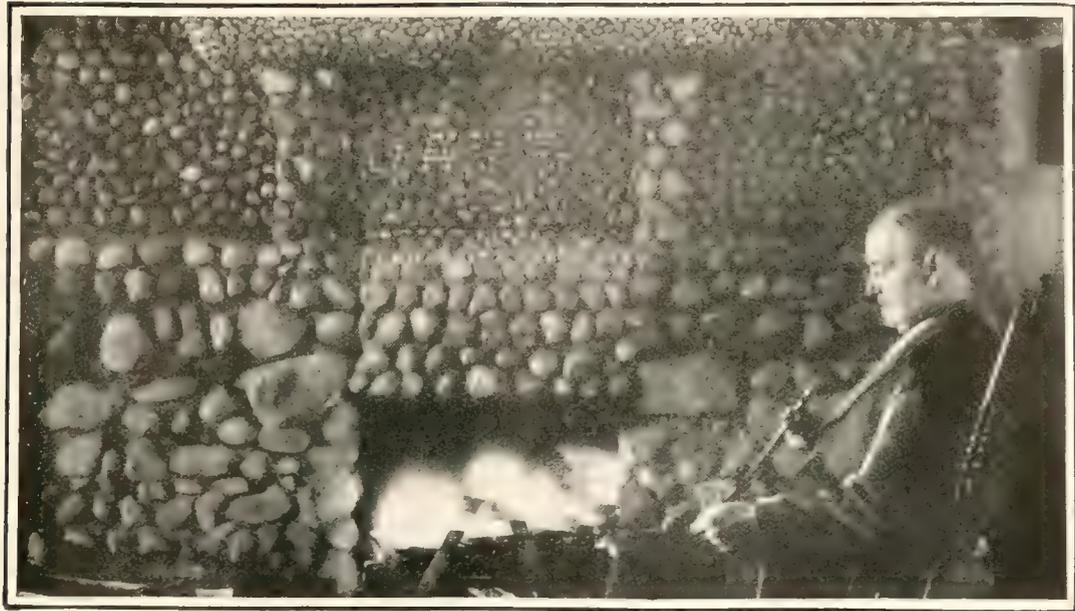

Then came those long days of waiting. “Will they NEVER come up?” A heavy rain packed the ground. Then I was presented with a new garden implement, a steel table fork; but it must be kept clean. With it I must keep the soil stirred. Finally a gentle rain came and, next morning, the ground was cracking and mother told me, “two little *baby plants* will be born.” And the next day; what a miracle! It was not *two plants*, but two groups of *triplets*, six new-born plants! Then came the instructions, “*never* let the ground *pack*, keep it loose, and give the plants water—in hot weather.” I was shown how to push the fork into the soil and keep the ground loose, and, in hot weather, I would hear mother calling: “Johnnie, your plants are thirsty; come and give them a drink.” Then she would give me a little pail with water, and a little tin cup, and oh! how my plants would *drink!* And they *grew* and went away ahead of any of dad’s; and when the crop was dug, he had nothing that could compare with mine! I did it RIGHT!

Dear “Boys:” Here is something you never had known, namely: THE SEED of The Davey Institute of Tree Surgery was sown 72 years ago, in front of the little cottage where I was born. That seed was: “Do it *right*, or not at all.” That kindly but manly voice went with me through boyhood’s days, and particularly through young manhood. As a result, I have never known what it was to be OUT OF WORK, but have frequently been in dire need of procuring others to help me execute what has

JOHN DAVEY

Father of Tree Surgery

John Davey, founder of the Davey Tree Expert Company, as he is today at nearly 77 years of age, at home before the fireplace he built with his own hands

been forced upon me. Notably was this true, 21 years ago, when I published the first issue of "The Tree Doctor." It bewildered my brain to find ways to procure efficient help to do the work I was called on to perform on "Sick Trees." Hundreds of young men wanted a "Job," but not one in ten knew HOW TO WORK; and worse yet they showed no inclination to LEARN.

Finally, after my son left college, and joined me, we decided to organize and form a training school; and we have been able to pick out the one-in-ten, or whatever proportion it has been, and under the management of this same son and his associates, to build up the wonderful organization to which you belong, and in which you, apparently, feel an honest pride, because you seem to have imbibed the spirit, "Do it RIGHT, or not at all."

I may here say that, in practicing this slogan from childhood, it has become an almost unconscious habit with me, in any and everything, to first learn the DO IT RIGHT, then add the speed. There are but few things more nauseating and disgusting than to see a young man shiftless and careless in his work. Personally, I would be unwilling to tolerate ANY one of such a character within our Organization. Such an one is a disgrace to himself and a positive damage to any concern that might keep him. But it gives me special pleasure to know that within our ranks there are very few, if any, of the class whose motto is, "GOOD ENOUGH!"

Your "Father John."

Tender Water Lilies

for artificial pools should be selected this month, although the actual planting may be delayed until early June. Tender Lilies are remarkably free bloomers, one plant often having six flowers open in a single day.

To my comprehensive list of tender varieties I have added a quartette of novelties originated at the Missouri Botanical Gardens, which are of exceptional merit.

My 1922 Booklet of Water Lilies and Water Plants describes these new Lilies as well as others that are extremely popular. Hardy varieties of natural pools, border plants and aquarium plants are also included in this edition. A copy will be sent on request.

Safe Economy IN A POWER MOWER

Strength is not sacrificed to lightness, nor durability to price in this mower, yet it is the handiest and most economical power mower on the market. Not built to meet a price but to fulfill a need in a highly satisfactory way. Compare the new low price of the Jacobsen 4-Acre Mower with the work it performs, look at its finished, sturdy construction, and you must admit it is a rare value.

THE "4-ACRE" POWER MOWER

The Pinnacle of Perfection in Power Lawn Mowers

Here are just a few of the outstanding advantages of the "4-Acre."

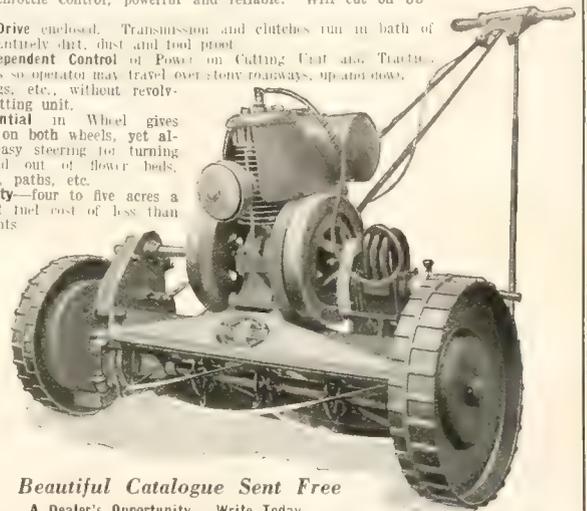

Motor specially designed, air-cooled, forced draft, magneto ignition, throttle control, powerful and reliable. Will cut on 35° incline.

Gear Drive enclosed. Transmission and clutches run in bath of oil. Entirely dirt, dust and tool proof.

Independent Control of Power on Cutting Unit and Tractor. Wheels so operator may travel over stony roadways, up and down, curbs, etc., without revolving cutting unit.

Differential in Wheel gives power on both wheels, yet allows easy steering for turning in and out of flower beds, bushes, paths, etc.

Capacity—four to five acres a day at fuel cost of less than 10 cents

Things and Thoughts of the Garden

MONTAGUE FREE

AT last a little controversy has been started because of opinions expressed on this page.

The following note has been received from Mr. Edwin Beckett of Aldenham House Gardens:

"I had pleasure in reading your notes in, I believe, the GARDENERS' MAGAZINE, regarding Aldenham. May I say, whilst writing, that you could have used the phrase as to our Trees and Shrubs numbering anything between 'Seven and ten thousand species and varieties' without fear of contradiction, for the statement made to you was quite accurate, especially as you will no doubt recall that your guide explained that such figure included plants of recent introduction that were still under collectors' numbers, and which for the time being were rightly classed as at any rate distinct varieties until determined by the leading botanists. Comparison of this figure with the Kew Hand List was rather out of the question, inasmuch as such work was last published in 1902, when their varieties were then numbered as about 4,500. That was nearly twenty years ago, since when wondrous strides in the direction of new introductions, and newly raised hybrids, have been made, and I think you will now agree that our figure is quite a probable one.

"Perhaps you will be able to call attention to these facts in the journal in question, as they certainly deserve this."

In the first place the statement made by our guide and quoted in the article referred to, was, if our memory is correct, that "the number of species and varieties was around ten thousand." This we understood to mean a few more, or a few less, than ten thousand—not possibly three thousand less.

We do not doubt for a moment that there are trees and shrubs at Aldenham under ten thousand or even more different names and numbers, but we are still doubtful whether these names and numbers represent well marked species and varieties, according to our conception of what constitutes a distinct species or variety. Some taxonomists, as is well known, are inclined to split up genera into innumerable species and varieties which many botanists and horticulturists would not recognize as such.

In connection with Mr. Beckett's contention that "Comparison of this figure with the Kew Hand List was rather out of the question * * *," we point out that our statement was: "In the 'Kew Hand List of Trees and Shrubs' published in 1902, the number of species of trees and shrubs cultivated there is given as three thousand." The number of varieties was not mentioned as at the time that information was not available. The fact that the Kew

Hand List was published twenty years ago and that a large number of new trees and shrubs were introduced during the last twenty years was recognized in the following sentence which Mr. Beckett perhaps overlooked—"It is scarcely possible, even allowing for the numerous new species of trees and shrubs introduced by Wilson and others during the past two decades, that the number of woody plants capable of cultivation outdoors in England has been increased to the extent of six or seven thousand."

We assume that Mr. Beckett means that the number of species and varieties cultivated at Kew numbered 4,500 in 1902, and not 4,500 varieties plus 3,000 species, in which case the above sentence should be amended to read: It is doubtful if the number of woody plants capable of cultivation outdoors in England has been increased in twenty years by about five thousand species and varieties.

Mr. Beckett is a great authority on trees and shrubs, the collection at Aldenham affords splendid facilities to enable him to form an opinion on this question and so it is quite possible that he is correct, but, personally we are not yet quite convinced.

Some time ago, on this page, attention was directed to some unusual common names for plants, and "Welcome-home-husband-be-you-ever-so-drunk" was cited as being the acme of unusualness. At that time the scientific name of the plant was unknown and the wish was expressed that someone might be able to enlighten the writer. Our trip to England indirectly led to the discovery of the correct name of this mysterious plant. On our return we found a book by W. H. Hudson, "A Shepherd's Life," which is concerned largely with the natural history of Salisbury Plain and the Wiltshire downs. It was, of course, read with intensified interest because of our visit to the region with which it deals. Great was our astonishment and delight on coming across a paragraph in which reference is made to the name, slightly different it is true, that had excited considerable speculation concerning the plant to which it could rightly be applied. The sentence in which it occurs may well be quoted. Hudson is referring to the roofs of the cottages on Salisbury Plain: "They are grown over with yellow stonecrop, that bright, cheerful flower that smiles down at you from the lowly roof above the door, with such an inviting expression, so delighted to see you no matter how poor and worthless a person you may be or what mischief you may have been at, that you begin to un-

derstand the significance of a strange vernacular name of this plant—"Welcome-home-husband-though-never-so-drunk."

Presumably the yellow stonecrop is none other than our old friend *Sedum acre*. It was mentioned in a preceding article that this queer name was used in some districts in Maine (we think it was in Maine), and here we have it cropping up again in Wiltshire. Its use is probably strictly local, for although we have spoken to many regarding it no one had had ever heard it before. It raises interesting speculations as to whether some inhabitants of Wiltshire County in times past emigrated to America and carried this vernacular name with them.

While on the subject of common plant names, it may be remembered that *Polygonum orientale* is sometimes called "kiss-me-over-the-garden-gate." Hudson in this book refers to "kiss-me-down-at-the-garden-gate," sometimes called pansy"! Another folk name that he uses is "Old Women's Nightcap" which so far we have been unable to identify with any plant.

* * *

It should be most gratifying to the gardener and to plant lovers in general to notice that, according to the daily press, the use of living plants in the decorations of the recently refitted "Mauretania" was considered a cheerful "innovation" by her passengers. The report states that "Her permanent floral equipment includes 82 palms, 30 bay trees, 100 ferns, and 500 potted plants, blooming in a great variety of color." It is doubtful if this can be regarded as an innovation, however, for we seem to remember reading some time ago that the ships in the England-Brazil service were supplied with greenhouses so that fresh flowers might be had on the dining saloon tables every day. One can imagine the amazement of the old-time seafarer if he could come to life and see how the products of the garden are kept in a state of health upon the billowy ocean.

The report concerning the "Mauretania" unfortunately omits to give information on a point likely to be of great interest to gardeners, namely: it says nothing whatever about the methods by which the plants are cared for, whether a gardener or gardeners are carried, whether the plants have to be renewed every trip, or if they maintain themselves in good health indefinitely on the ocean.

On our recent trip to England on board the "Orbita," we were struck by the healthy appearance of the plants used on the dining saloon tables and in the various entrance halls. Much to our amazement, inquiry of the chief steward elicited the fact that these plants had not been renewed but had been placed in the ship at the commencement of trans-Atlantic service about three months before. He stated that one of the stewards was entrusted with their care, and they certainly reflected great credit on him. Most of these plants were of foliage type, such as palms, Crotons, and ferns. There were some plants of Dusty Miller (*Centaurea candidissima*), growing on the center tables in the saloon well away from the port holes, that were weird and ghost-like, but not unattractive in their etiolated condition due to lack of light.

The use of living plants in the decoration of ocean liners may open up possibilities for the gardener of a roving disposition who might gain much pleasure in tending sea-going vegetation and from the opportunity to entitle himself Head Gardener of the "Mauretania," "Homerick" or "Olympic," as the case might be.

* * *

Probably nothing in the garden at this season of the year (late April) evokes greater admiration than the various spring bulbs when they are naturalized in grass. This is a side of gardening that can be carried out to

greater advantage on private estates than in gardens to which the general public have access, as in a private garden there is less danger of vandalism and theft. Of course, flowering material in private gardens is not always immune. We remember that at Warley Place Gardens where *Narcissi* and other bulbs are naturalized in the grass in enormous numbers, that elaborate precautions were taken during their blooming season to prevent them being stolen. The flowers were visible from a public road, and as this garden is located only 18 miles from London, it would be quite easy for persons from the wicked metropolis to come out in autos, load up with flowers, and dispose of them in Covent Garden market. The flowers were therefore hedged about by wires, which, on being touched, would cause a gun to be fired, notifying the watchman of an intruder.

In public gardens in this country, especially those near the large cities, it is difficult to have anything in the way of a natural plantation of such bulbs as *Narcissus* and *Tulip*, because many of the visitors jump to the conclusion that they are "wild flowers" and consider it their privilege to pluck them at their own sweet will. Apropos of this subject, it is interesting to recall what a former Director of the Royal Gardens, Kew—Sir William Thiselton-Dyer—said concerning conditions there. In his preface to W. J. Bean's book, "The Royal Botanic Gardens, Kew," he has words to the effect that the avoidable damage at Kew, even on a holiday when it is thronged with people, could be covered by the expenditure of a few pence. He explains this by saying that Kew possesses the "grand manner," which can be inherited but not acquired, and implies that visitors have almost a feeling of awe when traversing its precincts which puts them on their best behavior. This may be so, but many would attribute the freedom from damage to the excellent supervision exercised by the thirty or more constables. Possibly when our public gardens here become mellowed with time and hoary with age, the general public will have a greater feeling of respect for the beauties in them and not feel that their happiness is incomplete unless they wantonly destroy or steal. In the meantime, educational methods and adequate policing must be our chief reliance.

MY GARDEN WITH WALLS

My heart a garden is, a garden walled,
And in the wide, white space near the gates,
Grow tall and showy flowers, sun-loving flowers
Where they are seen of every passer-by,
Who, straightway fanning on, doth bear the tale
How bright my garden is, and filled with sun.

But there are shaded walks far from the gates,
So far the passer-by can never see
Where violets grow for thoughts of those afar,
And rue for memories of vanished days;
And sweet forget-me-nots to bid me think
With tenderness—lest I grow either cold
And hard as women grow who never weep.

And when sometimes I fear that love is dead
And sorrow rules as king the world's white ways,
I go with friends I love among those beds
Where friend and flower do speak alike to me,
Sometimes with silences, sometimes with words.

Is then I thank, my God for those high walls
That shut the friends within, the world without,
That passers-by may only see the sun,
That friends I love may share the quiet shade.

—The *Nones Garden* Wiltshire

Hardy Perennials for the Garden

JOHN JOHNSON

NO class of plants are in greater public favor or in greater demand than the hardy perennials. For this reason it might be justifiably claimed for them that few other plants equal their importance in the gar-

of so-called "Newer Perennials" comprising names so familiar as to serve only as a most vivid reminder of one's boyhood days. Were this the subject of our text it might be discussed at greater length, but to continue would defeat our aim.

The mixed border always has been and will probably continue to be the most favored resort for the disposition of hardy perennials, but an entire garden area embracing native landscapes devoted exclusively to their culture is something which has yet to be fully appreciated here in America. Despite the popularity of the herbaceous border there can be no question as to the advantages which a perennial garden offers in the way of mass plantings. The gorgeous effect of bold masses is, after all, the pertinent method of growing perennials. Certain kinds planted as single specimens are insignificant, but the same when grouped are very beautiful. Of course what appeals to one might not always so favorably impress another, and the method of planting is therefore largely a matter of individual taste. To make the best of the material at hand is the real question, and it is safe to assume that the arrangement of a perennial planting reflects the personality of the owner in the same

A view of the perennial garden on the estate of Mrs. J. A. Spoor, Pittsfield, Mass. The border plantings comprise irises and peonies for early summer bloom, followed by delphiniums, phloxes, veronicas, physostegia, etc., and rambler roses trained on chains in the background.

dening world of today. The ease with which most of them are grown, disparity in height, habit of growth, color and the varied conditions under which they thrive, commend them to all garden lovers, particularly beginners who would grow flowers at a minimum outlay of time and money. On account of the steady and ever increasing demand for hardy perennials it is not surprising that vast improvements have been wrought among certain kinds during recent years.

The once despised Michaelmas Daisy has undergone such transformation at the hands of the hybridizer that it is now classed among the most desirable of perennial plants. Delphiniums too, always stately, have been wonderfully improved by careful hybridization and selection. *Astilbe* and *Aquilegia* are plants whose beauty have been greatly enhanced with the course of time. Be this as it may, it is nevertheless amusing, and to some extent provoking, to the garden enthusiast who has been closely associated with gardens and gardening all his life, and who, perchance, might have striven to keep in touch with much really new, to see listed in our catalogues under the title "Novelties" so many plants that were favorites a quarter of a century ago. This is regrettable in so far as it may sometimes prove misleading. Only the other day there came to my notice an abridged list

measure as does the interior decoration of the home. There are those who seem to abhor repetition of the

Another view of the perennial garden which is on a steep hill overlooking Lake Onota. The main pathway passing through the arbors, illustrated, leads to the boathouse by the lake.

same plant or group along a border, while others would deem such repetition necessary to maintain proper balance. When a border is straight and narrow, I believe the best effect may be had by using a few plants or groups of the same type and color at given intervals. In a border of irregular outline, or one of good width, repetition is less needful. Perennial plants are so numerous and choice that there is little excuse for stereotyped methods of planting. Nothing is more disappointing than to enter a garden in which one border typifies the rest. This condition every gardener should try to avoid if he would have his garden give real pleasure. Again, so many people having a fondness for a certain plant will put it here, there and everywhere, and thus mar the interest of a garden. Of course, no matter what pains is taken in planting it will probably take years of study and observation to get just the desired effect, and this is one of the real pleasures of growing perennial plants—striving to get better results each year.

Delphiniums rank among the best hardy border plants. There are several special of the perennial delphiniums, ranging in height from 1½ feet to 8 feet. Their habit of growth is striking and the stiff spikes of bloom are in most intense shades of blue, as well as in mauve, purple, sulphur, white and scarlet. Among the dwarfed kinds are *D. chinense*, 2 feet, blue and white varieties; *D. cardinale*, 3 feet, scarlet flowers in August. A handsome plant but not a long liver, *D. nudicaule*, 1½ feet, orange scarlet, and flowers in July. The noble hybrid forms, however, are of surpassing beauty when well grown. They require a deep rich soil, free from fresh manure which has a tendency to breed disease, but the ground should be abundantly rich nevertheless. Good varieties are: Amos Perry, Hugo Portman, King of Delphiniums, Queen Wilhelmina, Lize and Rev. E. Lasceles. No plant has been so greatly improved of late years as the delphinium. New varieties come to light annually and it is both easy and interesting for the amateur to raise seedlings each year and retain varieties of merit. Delphiniums should be cut down immediately after flowering to insure succession of bloom. Established plants give two crops of bloom, while one year old plants flower more or less the whole season.

The peony ranks high in popular favor. There are two distinct types of peony, one of a shrubby nature, *P. Moutan*, called the tree peony, and the other a strictly herbaceous plant. Both are extremely hardy, showy, and easily grown. A deep rich soil suits them and they should be well supplied with moisture at all times, especially during the period of flowering. Peonies are somewhat accommodating, as they will endure full sunlight or a partially shaded position. They, however, resent to some extent disturbance at the root, and for this reason established plants should not be lifted more often than is absolutely necessary. When transplanting must be done it is just as well to remove the old soil from the tubers and give the plant a fresh start in rich soil. Varieties are very numerous and range in color from white to deepest crimson. There is also great diversity in form and size of the blooms and the aspirant who is looking for the best would be well advised to visit the establishment of a specialist and make a selection while the plants are in bloom. After flowering the foliage always looks well and for this reason peonies are given wider usage than any other hardy perennial.

Astilbe, erroneously called *spiraea*, has always been held in high esteem. For the margin of streams or ponds it is a most desirable plant. It is also a splendid border plant and may be used for forcing in pots for which purpose nearly all varieties are very suitable. No matter where grown, astilbes should never want for water at

the root during active growth. As garden plants, the value of astilbes has been greatly enhanced by the introduction of many beautiful hybrids. They grow from 3 feet to 6 feet in height according to the variety and flower during July and August. The *Arcndsii* hybrids are among the most striking: *A. Ceres*, rosy lilac in color, about 4 feet in height; *A. gloria*, similar in color but finer than the foregoing; *A. Juno*, rosy violet and a very handsome plant; Pink Pearl, dense panicles of a delicate pink shade; *A. Venus*, deep rose, tall and branching spikes; *A. Davidii*, also tall and a striking plant with good foliage, and flowers reddish-purple, not an old plant but already the foundation stock of many of the very best hybrids; *A. Mochheimi*, similar in habit to the last named, but the flowers creamy white in color. Peach Blossom and Queen Alexandra are pink varieties somewhat dwarfed in habit and flower earlier than the above mentioned.

The perennial aster is popularly known as Michaelmas Daisy or starwort. Here is a native plant which is gradually finding its way into American gardens and rightly so, because it possesses real merit as a garden plant. This aster has received greater attention at the hands of the English hybridizers than probably any other perennial plant. The different species and varieties vary in height from 2 feet to 8 feet, and can therefore be put to many and varied uses in the garden. The various shades of color in the starworts are too well known to quote, but it must be conceded that the newer hybrids have more intensified coloring and larger flowers than the species. Good varieties are King George V, Robinson V. C. Louvain, Serene, Edwin Beckett, Mons, Brightest and Best.

Heuchera (Alum Root) is a compact plant with pretty bluish-green foliage, fine for a position near the front of the border as it is practically evergreen. There are several varieties of *Heuchera sanguinea* which have coral red flowers. H. Nancy Perry has pink flowers, and is perhaps the finest form.

Aconitum is a very satisfactory plant for the border as it does well if planted in full sun and a little better perhaps in half shade. The color of the flowers is for the most part in shades of blue or violet, although there is a white variety and one, *A. Napellus* var. *bicolor*, with blue and white flowers. The different varieties bloom over an extended period, from July until late October. The best varieties are *A. autumnale*, *A. Fischeri*, *A. Wilsoni*, and several named sorts of *A. Napellus*. They vary in height from 3 feet to 8 feet.

Achillea is a perennial useful as a border plant as well as for cutting. It thrives in ordinary soil and either in sun or half shade, though it prefers the former. The outstanding varieties are *A. millefolium roscum*, and *A. Ptarmica* var. The Pearl. They are of rather rampant growth and increase rapidly by underground runners and require drastic treatment to keep them in bounds.

Anchusa is a useful plant on account of the unusual color of the flowers. *A. italica* var. Dropmore, a deep gentian blue, and the variety Opal has flowers of clear sky blue.

There are many artemisias in cultivation although the variety *A. lactiflora* is by far the most worth while. It grows 5 feet to 6 feet tall and has branching spikes of creamy white flowers the end of August to mid-October. It should be in every perennial border.

Boltonia is a tall growing plant resembling the Michaelmas Daisy. The varieties *B. asteroides*, white, and *B. latisquama*, pale lavender, are the best. Flowers in September and October, and is good for naturalizing or planting in the shrubbery.

Campanula is a bell shaped flower and one of the

most useful border plants, varying in height from a few inches to 5 feet, and not particular as to soil or situation. *C. carpatica* grows about 1 foot in various shades of blue. There is also a white form, *C. glomerata dahurica*, rich purple, very effective in mass, spreads rapidly, grows 2 feet and flowers during June and July. *C. lactiflora*, pale mauve, large flower heads, is a fine border plant flowering from June to August; *C. lactifolia* has tall spikes of drooping bells, blue-mauve; *C. persicifolia* has large bells and pale blue flowers. There is a white form, also one with double flowers, which is the most desirable of all. Many of the dwarfed kinds, such as *C. pumila*, *C. rotundifolia* and *C. muralis* are suitable for rockery as well as for edging.

Caryopteris incana (*Mastacanthus*) is a sub-shrub, resembling spiræa, with lavender flowers and grows about 3 feet, and is a very desirable border plant. It may be used in front of shrubbery.

Centranthus (Valerian) is a perennial which thrives in poor soil and grows from 1½ to 2 feet, with dense heads of tiny flowers, red, pink and white. It succeeds best grown as a biennial or may be flowered from seed sown early in the year. It is quite distinct from *Valeriana officinalis*, which grows 5 feet and is a veritable weed unless kept in bounds.

Cimicifuga is a handsome plant with good foliage and graceful spikes of bloom, flowering late in the Summer and early Autumn. *C. cordifolia*, the earliest of the group to flower, tall erect spikes of bloom in August; *C. racemosa*, a good variety with drooping racemes; *C. simplex*, the last to flower and not quite so tall as the above. Of handsome foliage and gracefully pendulous flower spikes, cimicifugas should be in every garden.

Clematis generally known as a climber, has several herbaceous varieties growing from 2 feet to 4 feet. *C. recta* is the best known, flowers white on long stiff stems, a very showy plant with single flowers. There is a double form also. *C. Davidiana* is a useful sort having blue clusters and flowers at a time when blue flowers are somewhat scarce during August and September.

Eremurus has tall spikes of creamy white flowers. A group of *E. himalaicus* gives a stunning effect against a background of green. *E. robustus* has rosy pink flowers borne in immense spikes. *Eremurii* flower in May and June.

The iris comprises a very extensive genus of herbaceous plants, chiefly hardy and with very bright and showy flowers. The flowering season of different irises is varied but most of them bloom from May to July, when the numerous varieties of *germanica*, *aphylla*, *squalens*, *pumila* and *lævigata* or *Kæmpferi* are in blossom. The genus is divided into two groups, the rhombatus types, or irises proper, and the bulbous irises, Xiphions or English and Spanish irises, as they are variously termed. Like the peony both species and varieties are so numerous that a selection of the best would be impossible. The bearded or flag irises are very popular and include *permanica*, *amara*, *aphylla*, *neglecta*, *pallida*, *squalens*, *variegata* and *lævigata* groups. Most of the irises thrive best in a sunny position and are not particular as to soil, but the *lævigata* section is naturally moisture loving and makes desirable plants for the hardy flower garden and could be greatly extended.

Democracy can never be extended by force, as you would fling a net over a flock of birds; but give it a chance and it will grow, as a tree grows, by sending down its roots into the heart of humanity and lifting its tops toward the light and spreading its arms wider and wider until all the persecuted flocks of heaven find refuge beneath its protecting shade.—Henry Van Dyke.

A BANANA PLANT

John S. Doig

A BANANA plant is illustrated here in fruit; the bunch, as shown in the illustration, carries one hundred forty fruits ranging from six to eight inches long, and of good uniform thickness. The flavor of the fruits is all that can be desired, as they are allowed to ripen on the plant. The plants were placed in their final quarters in August, 1920, from ten-inch pots; in August, 1921, they showed the bunches; on December 20, 1921, I cut the first fruit. As soon as the fruit has been all cut off, the old plants will be discarded and young plants, which are coming along nicely in ten-inch pots, will take their place. The box in which the two plants are growing is about

A specimen banana plant.

four feet wide, two and a half feet deep, and ten feet long. The compost consists of good friable loam, cow manure, and bone meal. The temperature ranges from sixty-five to seventy-five degrees at night, and is of a moist nature. The glass is slightly shaded during the hot months, but after the fruits are fairly well developed, the shading is removed. These plants have been a source of great satisfaction and interest to the owner, and of much interest and wonderment to many visitors.

DEVOTED

American business men are devoting so much time to golf they may soon get to the stage suggested by the following Scottish story:

"It's grand weather for golf we're hae'ing th' noo," remarked Sandy to Jock. "I'll go ye a run on the links in th' mornin'."

"In th' mornin', ye say?" replied Jock.

"Aye in th' mornin'," replied Sandy.

"Ah, weel," said Jock, "I canna miss a game o' golf. I'll go ye." Then after a long pause he added: "But I had intended tae get married in th' mornin'."

Sweet-Scented Flowers

FLORUM AMATOR

WE are accustomed to speak of flowers as pretty, dainty, beautiful, handsome, and sweet-scented. While the application of the other adjectives is somewhat a matter of taste there are in fact comparatively few flowers to which the word sweet-scented can be fittingly applied.

SWEET-SCENTED ANNUALS

Of the fragrant annual flowers which we raise from Spring planted seeds, Sweet Peas are deliciously sweet-scented even beyond the degree which the simple word "sweet" conveys to us. Some varieties seem to give forth a healthier and more agreeable perfume than others. If we plant the varieties separately and label each, it is indeed interesting to compare the fragrance of the flowers when freshly picked, and to note which exhales the most agreeable and which the heaviest perfume, and again to make the same comparison after the flowers are several hours old. The Sweet Pea is one of the flowers in which unusual beauty of form and color and a delightful odor are combined.

Mignonette has a peculiar fragrance which is pleasing to many, but which has always seemed to us to be too highly praised. The old time variety, *odorata*, has a more pronounced and pleasanter fragrance than many of the modern larger flowered varieties, though some of them are quite sweet and their flowers much larger and prettier than those of *odorata*; in this class are such varieties as Machet and Goliath. We may note here that the Latin word, *odorata*, meaning sweet-scented, is used as the specific name of many kinds of flowers, for example the Sweet Pea is *Lathyrus odorata*; the Mignonette, *Roseda odorata*; the Pond Lily, *Nymphae odorata*. Were it not for its fragrance we are inclined to think that Mignonette would be a little noticed flower, but because of this quality it is an old favorite. Tennyson who in his poems mentions more flowers than any other English speaking poet, except Shakespeare, says in "The Miller's Daughter":

"For you remember you had set,
That morning, on the casement's edge
A long green box of mignonette,
And you were leaning from the ledge
And when I raised my eyes above
They met with two so full and bright,
Such eyes! I swear to you, my love,
That these have never lost their light."

Stocks are an annual easily raised from seeds. These produce long spikes of flowers, some double and rose-shaped, others single in several pleasing colors, and having a delightful clover-scented perfume. Stocks produce their best flowers in the cool Spring or Autumn days, not in Summer's scorching heat. There is, we think, no other flower which combines stateliness, beauty of color in the rose, pink and purple shades, and entrancing sweetness in a greater degree.

The Heliotrope, a flower whose well-known and exquisite perfume needs no defining, as the meaning of its name indicates, unlike stocks, loves the long, hot Summer days and luxuriates in the full light of the sun. This flower with its varying shades of purple is a favorite not only with mankind, but we have often noticed when walking in our flower garden, has for lovers the bees, butterflies and humming birds as well. Strictly classed, the Heliotrope is a tender perennial, but plants from seeds will bloom the first season.

The perfume of Wallflower, though not as pro-

nounced as that of Stocks, is unique and so pleasant that it has made that flower both an old-time and present-day favorite not only in England but also in the United States. Wallflowers resemble single-flowered Stocks in form but not in color, but like Stocks are at their best in Spring and Autumn. The botanical name of Wallflower is *Cheiranthus Cheiri*. Strictly speaking, Wallflowers are perennials but early Winter-sown seeds will give plants which will bloom the following Christmas under glass. The botanical name of Stocks is *Matthiola incana*, variety *annua*, but Stocks and Wallflowers are closely related.

In flower from mid-Spring till the snows of November whiten the ground, *Alyssum maritimum*, because of its delicate and delightful fragrance well deserves its common name, Sweet Alyssum. The white flowers of this *Alyssum* are indeed small but very abundant. For bordering flower beds, for window and porch boxes, and hanging baskets, Sweet Alyssum is excellent.

Sweet Sultans, *Centaurea imperialis*, have several qualities recommending them strongly to the favor of flower lovers besides their delightful fragrance. The exquisitely fringed flowers in lilac, pure white, rose-color, and purple are carried high above the foliage on long, stiff stems and if cut when partly open, will last longer than almost any other flower in water, not infrequently from eight to ten days. Sweet Sultans too, like Stocks and Wallflowers, give us their finest blooms in the cool days of Spring and Autumn, and we should sow the seeds either very early indoors to produce plants for setting out in the garden early for Spring flowering or sow in mid-Summer for plants for Autumn flowering or both.

No one of our annual flowers, perhaps, has been more improved in its range of colors than that old-fashioned flower, Sweet Scabious, *Scabiosa maxima plena*. One of its old-time common names was Mourning Bride given to it obviously for the reason that its flowers were then of one color mostly, and that color such an intense, deep crimson as to look almost black. The modern Sweet Scabious, however, is not confined in color to a nearly "melancholy black," but bears blooms of white, light-blue, cerise and golden-yellow. Sweet Scabious has a fragrance which is not only pleasing, but also "that is different" and like Sweet Sultan carries its flowers on long stems, which makes it valuable for cutting.

When a rather large bushy plant reaching a height of two or three feet can be used to advantage in our garden beds or borders, among those whose flowers have a pronounced but pleasing smell, *Nicotiana affinis* is a candidate for the position. *Nicotiana* is a profuse bloomer throughout Summer and Autumn. The species, *affinis*, bears white flowers, but the hybrids of *affinis* give us blooms in shades of purple, red, violet and pink as well as white. The common name of *Nicotiana* is "Flowering Tobacco."

Mimulus moschatus is the Musk Plant. *Mimulus* is really a half-hardy perennial rather than annual, but will bloom the first year from seeds sown early. This plant prefers a moist, shady situation, as can be clearly seen from where our native species, *Mimulus ringens*, is found growing. The musk-like scent of *Mimulus moschatus* lies in its foliage rather than in its small yellow flowers. This is an excellent plant for hanging baskets.

Marguerite Carnations, like the "Perpetual-flowering" Carnations so much grown under glass, have a remarkable range of beautiful shades of color and of variegations

and an exquisite fragrance. This type of garden Carnation has the merit of coming into bloom in about three months' time from seed sowing—that is, seeds sown in April or May will give flowers in July and August.

There is another type of garden Carnation known as Chabaud's Carnations, marvelous for size and colors and the sweet scent of their blooms. Seeds of this Carnation, however, must be sown indoors in February to produce plants which will bloom in our garden in Autumn, but they are worth waiting for, and when open their flowers rival the finest blooms of the Perpetual-flowering Carnations.

SWEET-SCENTED PERENNIALS

Some perennials are tender, others hardy. To the former class belongs *Aloysia citriodora*, whose flowers are indeed insignificant, but the lavish citrus-perfume of the foliage is very refreshing and gives to this plant its specific name, *citriodora*, meaning citrus-scented, and its common name Lemon Verbena. Sprays of Lemon Verbena even when the leaves are dry retain in a notable measure their agreeable perfume, especially when confined in chests of clothing. The dry foliage of this plant is used in potpourri. Lemon Verbenas can be raised from seeds planted indoors in Winter and, if planted out in the garden after Spring frosts are over, will make plants of considerable size the first season.

The double-flowered, hardy, Grass or Spice Pink, *Dianthus plumarius nanus flore pleno*, the highest and most pleasing evolution from the dear old-fashioned Clove Pink, has a marvelously pleasing clove-like perfume of which we never tire. The colors and markings of this *Dianthus* are as—*amæna* the Romans used to say—pleasant to the eye, as the perfume is—*suavis*, the Romans said—agreeable to our nostrils.

There is another *Dianthus*, resembling to some extent, but yet quite different in its inflorescence from the Grass

Pink, but like it is an old-time favorite much improved by modern culture. This every flower garden should contain. This plant is the *Dianthus barbatus*, commonly called Sweet William, some William indeed was greatly honored when his name was given to this sweet-scented flower, whose blooms vary in color from white to deepest crimson, and revel in pretty combinations of colors. There are now, thanks to our floriculturists, annual as well as perennial or strictly speaking biennial, Sweet Williams.

There is an old-time sweet-scented perennial, little seen now in flower gardens, *Valeriana officinalis*, commonly called Valerian, and also Hardy Garden Heliotrope. The showy heads of rose-tinted white flowers of this plant appearing in mid-Summer have a pronounced and delicious heliotrope smell.

There are several sweet-scented perennials, bulbous or semi-bulbous mostly, which we will not describe in detail, namely, some of the hardy lilies, especially *Lilium candidum* (Annunciation Lily), *Hemerocallis flava* (Yellow Day Lily), *Convallaria majalis* (Lily of the Valley) and *Funkia cordata grandiflora* (Plantain Lily).

Suppose, if you please, that we had all of these sweet-scented annual and perennial plants growing in one garden, and they were all in leaf and in bloom on the same day, and pad and pencil in hand we should, as we tested the smell of each one with our olfactory nerve, try to describe it, do you think we would succeed?

Another question of interest to us and perhaps to others is this: Do we remember and can we recall a smell? For example, can we recall the smell of a Heliotrope flower, which we smelled a year ago just as we can recall the lineaments of the face of a friend we met last year? Apropos of this question, Owen Meredith says in "Aux Italiens":

"And I swear as I thought of her thus in that hour,
And how after all old things are the best,
That I smelled the smell of that Jasmine flower,
That she used to wear in her breast."

Flowers as Teachers

BERTHA BERBERT-HAMMOND

*Were I, O God, in churchless lands remaining
Far from all voice of teachers or divines,
My soul would find in flowers, Thy ordaining
Priests, sermons, shrines.—Horace Smith.*

IN an unmistakable manner do flowers, those silent but persuasive teachers, bring home to us in their own sweet, convincing ways, many lessons and truths. In most instances these lessons are so plainly indicated that there is not the slightest difficulty in observing and comprehending the truths to be learned. In the language of another:

*There are the little books of bloom
Whose pages printed in perfume
Hold lyrics in a language known.*

The shy violet, hiding from view, teaches sweetness and humility; the wild columbine, growing on a rocky ledge with barely enough earth for a foothold, shedding fragrance and beauty, speaks of courage. The dainty snowdrop and other harbingers of Spring breathe of resurrection, and evergreen leaves typify everlasting life.

Because, suggested by some prominent characteristic, certain plants have become associated in the minds of people in general with human virtues. The stately white lily is universally acknowledged to be a symbol of purity,

the orange blossom of chastity, the forget-me-not of love, the ivy of fidelity, the nettle of cruelty, the weeping willow of melancholy, and the trembling leaves of the aspen for lamentation.

There is an old legend to the effect that when God walked in the Garden of Eden, viewing the beauty He had created, all the flowers and trees, with the one exception of the Aspen, bowed in homage and love, and that now in penitence, wherever the Aspen tree is found, its leaves tremble and sigh all the time.

That in olden days meanings were attached to "green things growing" is evident from the custom of crowning heroes with wreaths of laurel (glory), patriots with oak-leaves and beauty with myrtle. The olive branch is an ancient emblem of peace and the passion flower for "faith." Innocence is expressed by the white daisy, the "day's eye," and pansy faces we know induce thoughts. As for the golden buttercups that so lavishly spangle our fields, they bring recollections of childish ways and

*We fancy a grassy meadow,
Where two little girls in blue
Are testing the rule and and saying,
"I like butter; do you?"*

(Continued on page 154)

Rhododendrons and Azaleas in the Garden

FRANK B. MEYER

OF rhododendrons there are more than two hundred species. Most of these have been found upon the Himalayas and the mountains of southwestern and western China, where have recently been discovered very many new species, some of superior loveliness. One or two species are native to northern China, two to central Japan, one to the Pacific states of North

Azalea lutea, Flame Azalea. (Courtesy of Harlan P. Kelsey)

America and five to the Atlantic, two to the mountains of central Europe and four to the Caucasus.

The ordinary reference to rhododendrons means some of the hybrids, the "handsomest of all broad-leaved flowering evergreens," so desirable because of their handsomeness, but in the eastern and northern parts of the United States generally not permanent or at least not satisfactory in their behavior. The explanation of this can be made most conveniently by quoting from Ernest H. Wilson's remarkable article that appeared in the *Garden Magazine* about five years ago. Centering largely around the Arnold Arboretum and written with New England conditions in view it contains mention of difficulties that can be discounted somewhat in a climate not so rigorous.

"The present day race of evergreen rhododendrons is essentially an English product and to better understand the subject let us briefly investigate its early history. No rhododendron is native of the British Isles and the first of the evergreen section to be introduced was *R. maximum*, indigenous to eastern North America, which flowered for the first time in London in 1756. A few years later (1763) *R. ponticum* was introduced and was followed in 1803 by *R. caucasicum*. The American *R. catawbiense* was introduced by John Fraser about 1809, and was common in gardens in 1838. Here are the beginnings of the rhododendron cult in England. Of these four species only two (*R. ponticum* and *R. catawbiense*) have played a major part.

"As a breeder *R. ponticum* has been the greatest asset and although its color is not good it

has proved extraordinarily adaptable in Great Britain and Ireland. This species grows wild in southern Spain and reappears in Asia Minor, in Syria and in the warmer parts of the Caucasus. These regions enjoy a much warmer climate than does New England and from our viewpoint it is a tender species and unsuitable as a breeder. Also, for the same reason, it ought not to be used as a stock for grafting; yet, unfortunately, it is *the* stock so employed. An appreciation of these facts explains in a large measure the doubtful hardiness and uncertainty of the present-day race of rhododendrons, since the blood of this tender species enters largely into the majority of the varieties.

"In the matter of hardiness the American *R. catawbiense* has been the greatest of all gifts in the realm of rhododendron and the hardiness of our present-day race depends almost solely upon the dominant influence of the blood of this species.

"*Rhododendron caucasicum* is a native of the higher Caucasus peaks and should be of much value to us since it is quite hardy in New England. Unfortunately it has been very little used by hybridists; but such offspring as *Boule de Neige*, *Coriaceum*, *Jacksonii* and *Mont Blanc* are very satisfactory plants in the Arnold Arboretum.

"Our native *R. maximum*, though the first species introduced to cultivation, has played a very unimportant part in the evolution of present-day rhododendrons. In a manner it has been disappointing; yet it is questionable if it has had a fair chance. To us its hardiness and late flowering are qualities of vast import."

Of the hybrids those that are most adaptable to the climate of Boston are: with red flowers, *Atrosanguineum* (very early), Charles Dickens, H. W. Sargent (late); with reddish flowers, *Caractacus*; with rose-colored flowers, *Roseum elegans*, Lady Armstrong; with pink flowers, Mrs. Charles Sargent, Henrietta Sargent; with dark purple flowers, *Everestianum*; with white or nearly white flowers, *Album elegans*, *Album grandiflorum*, *Catawbiense* (very early). But near Philadelphia at

Rhododendron catawbiense, Catawba Rhododendron.

(Courtesy of Harlan P. Kelsey)

Lindhurst, the estate of Mr. John Wanamaker, whose capable superintendent, Mr. John H. Dodds, is authority for much that is contained in this article, the hardiest of all has been found to be one not in Mr. Wilson's list, namely Kettledrum. In addition to this one the book, *The Complete Garden*, names eleven others as hardy in northern Ohio.

Such then are the present limitations to increasing the variety of broad-leaved evergreen rhododendrons in our gardens.

Of evergreen rhododendrons with small or comparatively small leaves, to quote Mr. Wilson again, "only a limited number have proved to be hardy and amenable to cultivation in this country. Many of them may be rooted from cuttings; but it has been found difficult to hybridize them with members of other groups. As a garden plant for this country *R. carolinianum* is by far the best species of this group and is one of the very finest of all broad-leaved evergreens hardy in Massachusetts. *R. minus*, better known as *R. punctatum*, which grows in the same region but at a lower level, is an old denizen of gardens; it has smaller leaves and flowers and a more open habit than *R. carolinianum*."

In northern Georgia is a form of it (variety *harbisonii*) with larger leaves and flowers in larger clusters, which may be expected to make a handsome garden plant. According to a recent bulletin of the Arnold Arboretum it is not yet in cultivation.

"The two dwarf rhododendrons *R. ferrugineum* and *R. hirsutum*, natives of the mountains of central Europe," Mr. Wilson goes on to state, "are unsatisfactory in New England; but three hybrids between them and the *R. minus* are valuable garden plants in this climate. One of these hybrids, *R. myrtifolium*, is a very compact round-topped shrub, from two to four feet in height, and as much through, with neat foliage and small pretty pink flowers. Another, *R. arbutifolium*, is a shrub of open spreading habit and forms low wide masses. The chief value of the plant is in its ability to cover either sunny or shady banks and for this it is admirably adapted. The third hybrid is known in gardens as *R. wilsoni*. It also spreads over sunny and shady banks which it covers in June with beautiful lavender blooms. From the cold regions of Manchuria and Korea come *R. dahuricum* and *R. mucronulatum*, which have deciduous leaves. Other early-flowering rhododendrons are *R. praecox* and its variety Early Gem. Both are evergreen bushes, much branched in habit and have pale to deep pink flowers. In favorable seasons, when the flowers escape the late frosts, these plants are very beautiful in Spring; but unfortunately this rarely happens.

"Valuable for the rockery and partial to sunshine are *R. racemosum*, *R. flavidum* and *R. intricatum*, three new comers from China. They are twiggy plants, growing from four to six feet high, and may be rooted from cuttings. These species are very floriferous Alpine plants, with small leaves and of neat and charming habit.

"The only other species of this group that need be mentioned is *R. micranthum*, also from China, which has clusters of minute Ledum-like white flowers and small leaves." But according to a recent bulletin of the Arnold Arboretum the Japanese *brachycarpum* is superior. The original plant of it, presented to the Arboretum by Mr. Francis Parkman, was lost in transplanting; but Mr. Wilson has sent large quantities of seed from Japan and soon its large pale pink or pale straw-colored flowers may become common here."

The usefulness and the charms of even these species as garden plants are not yet sufficiently appreciated by us. Our English cousins are more fortunate. A writer in a recent number of *The Gardeners' Chronicle* in fact exclaims that if his choice were confined to six varieties of the rhododendron they would be none of the popular hybrids, but (1) the pale yellow *campylocarpum*, (2) the best lavender-blue form of *angustinii*, (3) the brilliant scarlet *neriflorum*, (4) *roylei* or *cinnabarinum*, (5) the lovely pink seven-lobed *fargesii* and (6) *Thompsonii* with its waxy crimson bells. These are worth recording here because, although they are not hardy in a climate like ours it is possible that from them may be developed hybrids to which may be imparted some of the ruggedness of constitution possessed by American natives with which they may be crossed. They are undoubtedly adapted, according to Professor Sargent of the Arboretum, to our Puget Sound region. There we may expect to find established in time examples of the widest range in variation of size, form, habit and color. There are some that are tall and tree-like, other that are epiphytic and some, like *R. prostratum*, that are carpet plants.

To widen the range even in our vicinity, one may enter among the azaleas, which are now regarded as merely a section of the rhododendron genus, and among which two species, *canadense* and *vaseyi*, both good garden plants, thrive best in a rather moist soil and in the neighborhood of open water. The former is the well known dwarf shrub that from Newfoundland to Pennsylvania and New Jersey covers large areas of swampy land with a sheet of rose-purple bloom, while the latter, also dwarf and of a more open habit, has pure pink flowers of perfect tint.

To a different section of the azaleoid rhododendrons belong thirteen species of which eight are native to the

Rhododendron cataebense growing wild at 5,000 feet elevation, western North Carolina.

(Courtesy of Harlan P. Kelsey)

Atlantic seaboard of the United States. Five of these, Mr. Wilson notes, are "all good garden plants which take kindly to cultivation and thrive in ordinary soil, in either open or shady situations, and no group of plants adapted to our climate surpasses them in beauty. The first to open their flowers are *R. canescens* and *R. nudiflorum*. Both have fragrant pale rose or pink flowers, of various shades, which appear before the leaves or just as they begin to unfold. The next to blossom is *R. calendulaccum*, the yellow azalea of the Appalachian mountain slopes, which opens its flowers early in June. The color varies from bright yellow to orange or shades of red and the beauty is heightened by contrast with the dark green leaves which are well grown before the flowers open. It is a rather slow growing but long lived plant, from eight to ten feet tall, and the beauty of its brilliant colored flowers is not surpassed by those of any other azalea. The yellow azalea is followed by *R. arborescens*, another inhabitant of the glades of the Appalachian mountains from Pennsylvania to Georgia, which blooms about mid-June. This is a tall shrub, growing from ten to fifteen feet high, with large pure white, very fragrant flowers, the beauty of which is increased by the bright scarlet color of the long exerted stamen-filaments and styles. The leaves are pale-colored and are full-grown before the flowers open. The last to flower is *R. viscosum*, the Clammy azalea or Swamp Honeysuckle, a common inhabitant of the swamps near the Atlantic seaboard, which does not open its flowers till July. It is a shrub of medium size, with small, very fragrant, pure white blossoms covered with sticky hairs and the leaves are often pale bluish especially on the lower surface. The plant is valuable for the lateness of its flowers, which continued to open for weeks when those of most shrubs are past." The Arboretum bulletin of May 9, 1921, adds *roseum*, "an even handsomer plant than *vaseyi*. Although first distinguished and named in France as early as 1912, it has always been confused with other species till quite recent years, and has never received the attention which it deserves. It is a shrub from three to fifteen feet tall with rose-colored flowers which open after the leaves begin to unfold and are more fragrant even than those of *viscosum*. This azalea is common in southern New England and southward to Virginia; it grows in western New York, northeastern Ohio, southeastern Illinois and the adjacent part of Missouri, that is in regions of limestone soil, and the fact that it can grow in lime makes it possible to cultivate it in parts of the country where other rhododendrons do not grow." A still later bulletin adds *anneliesæ*, probably a chance hybrid of *arborescens* and *calendulaccum*, more fragrant than the latter, of orange-red and clear yellow and valuable because it flowers later.

One east Asiatic species, *japonicum*, is perfectly hardy and its large flame-colored flowers are very handsome. It and *R. schlippenbachii*, pronounced by the English writer referred to before as "peerless," broad in limb, pale clear pink and delicately spotted with green, are included among the eighteen best new shrubs at the Arnold Arboretum by the bulletin of July 15, 1920. *Japonicum* mated with *R. sinense* at the Hunnewell estate has become the parent of *R. kosterianum* Miss Louisa Hunnewell, of which the following judgment has been made at the Arnold Arboretum: "If anyone in the United States has raised a handsomer shrub it is unknown to the Arboretum. Its large clusters of orange-colored flowers open as the leaves unfold." Another, *luteum*, incorrectly sometimes named *flavum* but commonly known as *Azalea pontica*, is not hardy in the eastern part of the United States. It is important because it has been used so much as a stock for grafting and in hybridizing.

The American species, Mr. Wilson thinks, should be used much more generally in the gardens of eastern North America; but it is difficult to procure them because very few nurserymen are willing to devote the time and the trouble necessary to raise them from seed, the only satisfactory way to propagate them.

In the absence of these plants and in ignorance of their value and beauty have been employed the so-called Ghent azaleas, a race of enchanting hybrids, but short-lived, indifferently hardy and not suited to the climate of New England, good for forcing purposes but not for the garden in the colder parts of the country. They are the hybrids of *pontica*, which bears bright yellow and fragrant flowers, and *nudiflora*, *viscosa* and *calendulacea* introduced from the United States into England and grown in large numbers at Ghent, Belgium. A somewhat hardier offspring resulted from crossing *R. sinense* and *R. japonicum* with the various Ghent azaleas. These *mollis* azaleas, not hardier in New England than the Ghents, can be grown in the vicinity of Philadelphia out of doors very well if they are given a little shelter. They are grown in dwelling houses in the winter and are very beautiful.

A third section of the azaleoids consists of the Japanese and the Korean. The most important is the scarlet-flowered *Kämpferi*, introduced by Professor Sargent in 1892 and, according to Mr. Wilson, one of the most valuable shrubs that the gardens of eastern North America have received from Japan. Like all the other azaleas mentioned before it is deciduous. It grows to a height of three to eight feet and is a blaze of color for one or two weeks in May, brightest in partial shade. It deserves a good place sheltered by trees, but not too near them, with favorable soil. An offspring from it and *amanum*, raised by Jackson Dawson, is called *Arnoldiana*. Its flowers vary in color. Being a dwarf it is good for the edges of beds and for rock gardens. A large Japanese species is *R. rhombicum*, which bears rich red-purple blooms. The Korean *poukhanense* is a very compact round-headed shrub, the rosy mauve or red-violet blossoms of which are delightfully fragrant.

Of Japanese azaleas the Kurume varieties, from the highlands of that Island Empire, have recently been attracting much attention that is richly deserved by their wonderful beauty and diversity of coloring. The Arnold Arboretum has exhibited remarkable specimens at the shows in Boston; but it is still too early to declare that any of them are for our gardens. Near Philadelphia Mr. A. E. Wohlert, of Narberth, who has paid much attention to the newer Japanese flowering trees and shrubs, has this past Winter been trying out of doors several thousand dollars worth of these handsome shrubs. At the middle of March his report was that the great majority were not promising well.*

Of evergreen azaleas the *amana* or *indica*, which flowers early, with bright rosy-purple blossoms, is hardy as far north as New York City. The finest form of it is known as *hinodegiri*, of beautifully symmetrical shape and which bears its bright scarlet blooms in great profusion. *Hinamayo*, resembling it in form, has larger leaves and its flowers are of a wonderfully clear shade of pink. It is almost evergreen.

ARRANGEMENT ACCORDING TO COLOR

As with tulips and peonies there is not much chance

* Since this was written the freezing during the night of April twenty-first has blasted those flower buds that were fairly well advanced and killed back the leafy tips; but, though the plants had been protected only by a slight natural growth of weeds, the bark of the stems has not been cracked nor the plants injured in any other way. In frames and under glass they are now rapidly recovering and will continue to bloom. The damage to the plants would have been less if they had been well sprinkled, early in the morning after the frost, with cold water.

that rhododendrons will clash if proper precaution is taken in placing the impure and glaring reds. For nice arrangement the hybrid rhododendrons may be divided into four large or main groups within any one of which the different varieties will harmonize fairly well, (1) the red, (2) the pink, (3) the white or substantially white, (4) the lavender and purple. Almost any of the whites may be inserted into one of the other groups, if that should be desired, or can be used in effecting a transition from one group to another. The chief point is that out of any one of the groups should be kept the purple-reds like *Caractacus* and Abraham Lincoln, the magenta-pink of *roseum elegans*, the dark magenta of *catawbiense grandiflorum* and the reddish plum of President Roosevelt or H. W. Sargent. Each one of these "dangerous" colors should be kept by itself or marked off by white.

With azaleas more care is sometimes necessary. *Poukhanense's* color does not harmonize with that of any other azalea blooming at the same time and so it should be kept away from all others to avoid a chance overlapping of blooms. *Hinodegiri* is of a shade so intense that it clashes frightfully with the *amara* and the *mollis* varieties; it can be used with white to make a very charming contrast.

WHERE TO PLANT AND IN WHAT SOIL

The answer to this question also has been framed very well by Mr. Wilson. "Evergreen rhododendrons are mainly woodland and in a measure also Alpine plants and they must never be allowed to get dry at the roots. A situation screened from the morning sun and sheltered from cold cutting winds and where the roots may be kept cool is essential to success. The strong sun in March, which draws moisture from the leaves when the ground is frozen and the roots perforce incapable of making good the loss, is a potent cause of death. This in conjunction with the tender strain in the present day race and the fact that the majority are grafted on the not hardy *R. ponticum* very thoroughly explains the disappointment experienced by American lovers of these plants, and especially those whose gardens are in New England.

"If practicable it is best to plant rhododendrons in association with trees, for by so doing they receive a measure of protection from the sun's direct rays. In thin woods or on the margins of such woods are good sites and if the situation is open and exposed a screen of conifers—Hemlock, White or Red Pine—should be afforded them. If the situation be such that the roots are kept cool by a thorough water supply the nature of the soil (always provided it does not contain lime) is of less importance than is often claimed. Where the White and Red Pine, Birch, Chestnut and White Oak thrive rhododendrons will grow. A soil free of lime, sweet, moist and porous and fairly rich in leaf soil is the ideal. A decomposed granitic soil rich in humus is excellent. In the absence of lime rhododendrons will grow in good loamy soil; but it should ever be remembered that they are humus-loving plants and require to be mulched with leaves and the soil enriched with leaf soil or sandy peat. It is usually assumed that peat is necessary in order to grow these plants; but as a matter of fact a far greater number of the species find a home on the humus-clad rocks and cliffs than in peat swamps.

"In regions where the seasons are milder than in New England these rhododendrons will thrive in positions more or less fully exposed to the sun; but no matter where they are planted they must never be allowed to suffer from drought. The root system of all rhododendrons is fibrous and scarcely descends more than a foot below the surface. Obviously a mass of fine hair-like

roots near the surface of the ground can not withstand drought and the need of a mulch of leaves is clearly shown. On account of their fibrous root system rhododendrons are easy subjects to transplant, provided this be done with a large ball of earth and due attention be paid to keeping them properly supplied with water afterward.

"The hardy members of the azalea section are all virtually deciduous and a majority will stand more exposure to sun and drier conditions than will their evergreen relatives; but drought has very evil effects upon these also. It is advisable to place these azaleas fairly close together and as a ground cover to plant different varieties of heather (*Colluna vulgaris*) and hardy heaths (*Erica carnea*, *E. vagans*), which are not only pretty in themselves but mask the ground from the sun's rays."

To grow rhododendrons and azaleas in limestone areas it is recommended there be made mounds of specially prepared soil. The lime will thus not be so apt to impregnate the site. But in such a situation particular care must be exercised to prevent the plants from drying out.

In agreement with Mr. Wilson's declaration that peat is not indispensable is the English writer quoted twice before; in heavy soils, if the right sort of peat be not obtained it may be absolutely deadly. Particularly if a plant has been grown by a nurseryman in peat is it apt to die when it is moved into a heavy soil where the climate is at all moist.

But at Lindenhurst it has been found that grown in the native soil alone the vigor is less, as is proven by the shortening of the stems. It has there been found best to prepare a bed for permanency by digging in in the Fall, to a depth of three feet, peat at the rate of one barrow-load to fifty square feet and one-half wagon-load of leafmold. The peat, however, should be that containing silver sand; the mucky peat from New Jersey serves well for orchids, but not for the plants here being written about. Alphano also has proven to be quite satisfactory; but it is not put so deep down. For the ordinary border there is dug in in the Fall, to the depth of a foot and a half or two feet, cow manure, well rotted, at the rate of thirty tons to the acre, and in the Spring a layer of leafmold two inches thick. A good dressing of decayed cow manure is applied every third year. Humus in the form of old sod or of any vegetation not sour improves the general conditions greatly.

To provide a mulch of leafmold it is not well to allow dry leaves in the Autumn to remain around the plants; the danger from fire is too real, as the superintendent of Lindenhurst has experienced upon an estate the owner of which declined his advice. Carted away to a pile and held down with a little manure, which is later forked into the mass, the leaves are within less than a year in condition to make an ideal mulch. For the Summer mulching of young stock Mr. Koster, of Bridgeton, New Jersey, advocates the use of cornstalks chopped fine; it provides coolness, retains the moisture and admits the air.

(Continued in the June issue)

You think that one hour buries another, but it is not so. You think that you have parted forever from the things that have passed by you. No, you have not. That which you have done is with you today; and that which you are doing will be with you tomorrow. When the mason carries up the wall, the course of the brick which he laid yesterday is the foundation on which he is laying another course today; and all that you do today on the structure which you are building, will remain as a basis for that which you do tomorrow.—*Beecher*.

Great Exhibition of Wild Flowers and Ferns in Boston

W. N. CRAIG

AN exhibition of native orchids completely filling the main hall of the Massachusetts Horticultural Society and staged by Albert C. Burrage, president of that society, attracted 25,000 visitors in May, 1921, and it was felt that many years must elapse before such an attendance would again be reached in Boston, but the great show of native ferns and flowers which opened on May 3 and closed May 14 so far surpassed last year's show in attendance that the 30,000 mark was passed on the fourth day and as many people viewed it as at such extensive and extended expositions as the Home Beautiful, automobile and food fairs.

The setting for the show was an ideal one. Criticisms have often been heard of Horticultural Hall for exhibition purposes, some of which are true, but when all walls are hidden as on this occasion, the height of the hall and the cool temperature, many degrees lower than the open air, and the freshness of the exhibits, a week after the opening, all go to prove that some credit is still due the design of the hall and the oft criticised building committee.

The visitor enters the hall via the loggia through a wide avenue of spruce trees reaching the ceiling, below his feet are soft sand, gravel and pine needles, and at once a "woody" odor assails his olfactory organs, that "piney smell" which so many tired city folks long to inhale for a week or two each Summer.

At the entrance end of the hall and facing the loggia is a delightful waterfall, not a tiny miniature affair, but one of at least six feet breadth in the center of a rocky promontory where sixty tons of rocks are effectively placed, and over that from a height of some twenty-four feet the water comes tumbling in a series of short dips at first and a final drop of fifteen feet. Three hundred gallons of water per minute pass over the falls, which at night are especially beautiful with a greenish light thrown from overhead on them. The water falls into a large pool and is carried by a stream to nearly the opposite end of the hall when it disappears in a pipe, flows back behind the rocks and is again pumped over the falls by an electric motor.

The wooden floor of the hall was removed to allow for the construction of the show and concrete beds were laid for the streams and pools over which a neat rustic bridge crosses near the falls. Bordering the stream are irregular borders resembling swamps covered with green sphagnum moss, and planted here are large vacciniums in flower, andromedas, osmunda and other ferns, *Cypripedium spectabile*, *habenarias*, *pogonias* and other orchids, *Sarracenas*, *droseras*, *calthas* and numbers of moisture loving flowering plants, naturally planted.

Around the sides of the hall and rising fifty feet in height are mountains heavily clad with pines, hemlocks, cedars, spruces and other evergreens, scattered through which are found the white dogwood (*cornus florida*), the shadbush (*Amelanchier canadensis*), the great laurel (*Rhododendron maximum*), mountain laurel (*Kalmia latifolia*), the sheep laurel (*Kalmia angustifolia*), *Viburnum dentatum* and other native shrubs and trees in flower, while at lower elevations among crannies and crevices, or on the sheer face of the moss covered rocks are masses of all the ferns native to Massachusetts, forty-seven in number, and near the base irregularly and tastefully placed are *cypripediums*, mayflowers (*Epigaea*), violas, asters, bluets, trilliums, hepaticas, *ranunculus*, anemones, bloodroots and numerous other wild flowers,

some eighty-three varieties in all. I failed to see an omnipresent friend, the dandelion and some others, probably because they are classed as aliens and not native, albeit they make themselves very much at home here.

The exit from the hall is through a dense avenue of spruces and so great is the attendance that except in the earliest morning hours a one way passage only is possible, and progress is naturally very slow. It is particularly pleasing to note the great delight of the thousands of city children over the delightful show, and it is worth a whole lot to watch their pleased faces, just as it is to see and hear the remarks of older people, once country dwellers, whose memories went back to the old country farms where their early years were spent. At this show they met many old familiar friends.

The plants used in this show were all forced in the greenhouses of Albert C. Burrage, of Beverly Farms, and much credit is due his able superintendent, Douglas Eccleston, and his corps of assistants for the skill in timing the exhibits and the good taste shown on the construction of the many charming features of the exhibition.

Illustrated lectures were given on New England wild flowers, their cultivation and protection as follows by the Massachusetts Horticultural Society and at each there was an attendance of between 400 and 500.

Thursday, May 4. Some reasons why wild flowers are rare, by Prof. Merritt L. Fernald, Howard University.

Friday, May 5. The conservation of our wild flowers, by Herbert W. Faulkner, Washington, Conn.

Saturday, May 6. The cultivation of native plants, by Dr. R. T. Jackson, Petersborough, N. H.

Monday, May 8. The naturalization of wild flowers, by Norman Taylor, Brooklyn Botanic Gardens, Brooklyn, N. Y.

At a meeting of the board of trustees of the Massachusetts Horticultural Society held May 8, the George Robert White gold medal of honor for distinguished services rendered to horticulture in the year 1922 was awarded to Albert C. Burrage. Mr. Burrage is serving his second term as president of the Massachusetts Horticultural Society and also of the American Orchid Society. In 1920 he made a magnificent monthly exhibit of orchids at Horticultural Hall, in 1921 he staged the great show of native orchids in May and was an extensive exhibitor of ferns, *Selaginellas* and orchids at the great tropical fern and orchid show in September, and last but not least the present notable show of wild flowers and ferns. Mr. Burrage is a very amiable and democratic gentleman, keenly interested in the advancement of horticulture and the award is well merited.

At the meeting of the American Orchid Society held in Boston on May 6, it was voted to hold a great national orchid show in Boston in 1924. The Orchid Society will offer on this occasion special gold, silver and bronze medals, and similar medals will also be offered through other societies who carry orchid classes on their schedules.

GARDENERS' CHRONICLE
286 Fifth Ave., New York

Beaver Lodge

The Country Estate of H. E. Partridge
Shell Lake, Wisconsin

THIS place was originally a spring invested swamp; much tiling and filling had to be done in order to gain a foothold. By taking advantage of the beautiful spring lake and its outlet several artificial pools were formed. As the soil below the surface is extremely cold, every specimen planted had to be carefully selected in order to be a success. Mostly native conifers from six to twenty feet high were used which were dug and transplanted with a frost ball, together with such conifers as will stand the trying conditions of twenty to forty degrees below zero.

Rocks and boulders played an im-

The side view of Beaver Lodge.

The front view of Beaver Lodge.

portant part in this semi-Japanese landscape. Placing them in a natural position, creating an aged appearance by sinking them nearly two-thirds and not omitting the

harmonious coloring of the rocks, a very unique effect was obtained. Mugho Swiss Mountain pines, the different sabinas, rock plants and hardy perennials were liberally employed.

The Japanese garden is not the only delightful feature of Beaver Lodge, but Mr. Partridge has followed the style now becoming very popular on American estates, of combining the vegetable and flower gardens which takes away the monotonous appearance of the straight rows of vegetables, and if properly arranged according to height, flowering season and color, adds attractiveness to the entire layout.

Theodore Wirth, the well known authority on landscape architecture, played a prominent part in the planning and laying out of the landscape and in 1914 turned it over to Charles Schroll, the

present superintendent, who together with his genial and Nature-loving employer still plan further improvements now that labor is more easily available.

Swamps and bogs have given way to velvety lawns and specimen conifers. The wooden bridge has given way to a beautiful scrolled concrete bridge. Paths surround the entire semi-Japanese plantation.

The same scene taken earlier in the season. Here the "stepping stones" across the creek are more distinct, which is a typical Japanese feature, as well as the arrangement of the rocks.

Beautifying Home Surroundings

ARTHUR SMITH

AFTER the completion of a house, the grading around it comes up for consideration. Very frequently a good deal of money is spent unnecessarily in this direction, and which could be put to a better use in making a garden, as in many instances the money is used in ways which do not increase nor create beauty. This waste is especially noticeable in the matter of terraces. Under no circumstances does a terrace in itself create anything but discord in the landscape. We have never been able to get the point of view of those—unfortunately numerous—people who find something pleasing in the idea of a terrace. Many, whose lawns were, or might have been made, the most beautiful of gardens, have spoiled them by terraces. For some unexplainable reason some persons are possessed with the idea that every house, no matter what its position should have a terrace, and they spend large sums forming terraces even upon level ground. Elaborate terraced gardens in the wrong place prevent the formation of beautiful lawns, although a good lawn is one of the most pleasing things in a garden.

An insignificant looking house with a fine, unbroken lawn gives invariably a better effect than a fine house with terraces in front of it.

When a house is erected upon ground considerably higher than its immediate surroundings, some terracing may be necessary to afford a sufficiently level space for a drive to approach it and to turn round, and in these cases a terrace becomes a necessary evil; as it is also when required for the formation of playing lawns. When such circumstances call for the existence of a terrace there still is no reason for the sharply graded slopes like a railway embankment. Sharp, green angles thus formed are the very height of unnaturalness.

After we have settled the essential approaches and levels in close proximity to the house, the natural form and lines of the earth itself are invariably the best to follow, and in cases where bad planning has been the reverse of this, it is often well to face any labor to get the ground back to its natural grade where it has been disfigured by ugly or needless banks, lines or angles.

The next thought is generally given to providing the house with some shade. Frequently this is overdone, and the house ultimately becomes so shut in that the necessary circulation of air is prevented and in the early Fall before the leaves drop the house is rendered dark and damp. This is more especially the case when such trees as the Norway and Silver Maples are used for the purpose. The dense shade these produce combined with their roots also create conditions which prevent anything else growing or thriving under or near them. From all points of view these two species should be discarded from home surroundings, as there are so many other kinds which not only give all necessary shade but which also possess many prominent features of beauty which these Maples do not have.

In providing shade trees several points should have consideration, especially with those who use their homes all the year round. There is of course the shade; then there are species conspicuous for their floral effects, followed in the Mountain Ash, as one instance, by brilliant berries; then there are the beautiful color effects produced by the Autumn foliage.

Autumn color affords us opportunity to have a landscape as spectacular and as gorgeous as in any other season, and this point should be remembered also in connection with shrubs.

The number of good shade trees without any objectionable features is large and while it is obviously impossible to mention all of them, we would like to call attention to the merits of a few of the least used kinds.

We have always thought that the Oaks should have a more prominent position among trees for this purpose. The fact that they have not is to a great extent the fault of nurserymen whose horizon is bounded only by the commercial side of the question, and it is undoubtedly a truism that when commercialism comes into competition with art, art always suffers. Grass and other plants will grow under Oaks when they will not under Maples, and their shade is sufficient for all purposes without creating darkness. The two best are the Pin Oak (*Quercus palustris*) with its graceful outlines and the Red Oak (*Quercus rubra*), the fastest growing, with broader leaves and more spreading branches; both are a brilliant spectacle in the Autumn. The Lindens are good, especially for large lawns, and their flowers give off a delightful perfume and are much loved by bees. The ruddy grown bark of the Lindens gives a very cheerful Winter note to the landscape.

From all the points of view by which one measures the all round beauty of a shade tree we know of none which comes up to the Sweet Gum (*Liquidambar styraciflua*). Its star shaped leaves afford a unique feature, and these in the Fall give wonderful kaleidoscope colors of bronze, orange, lemon and scarlet. Among flowering trees there are the Horse Chestnut and Yellow Wood (*Cladastris virgillia*). *Catalpa speciosa* is another one conspicuous for its floral effects, but the dropping of its seed pods makes it a dirty lawn tree.

In connection with places of somewhat small area, the question of using fruit trees, apples, pears and cherries, for shade purposes should be considered. Not only are there no reasons against their use for this purpose, but several may be advanced in their favor. They may be grown to give as much shade as any other tree of the same age; no trees are more beautiful when in flower, and it is scarcely necessary to emphasize their beauty and usefulness when in fruit.

Considered as a whole the judicious planting of shade and ornamental trees not only affords an abundance of comfort and pleasure, but it enhances the value of real estate more than an equal amount of money spent in any other manner. Persons looking for investments in homes are not attracted, but repelled, by barren home surroundings. There is always something charming in the smallest cottage having a good selection of trees properly placed about it.

Trees, as apart from shrubs and herbaceous plants, should be the first things placed in position. They should not, however, be scattered about the entire grounds, planted in rows, orchard, or checker-board fashion. All grounds, no matter how large or small, should have an open space for lawn, and trees should be located, placing the trees, in addition to those near the house for shade, along the outer lines of the property, with groups for any necessary back-ground or screen. In all cases it is important to avoid planting too many trees, and in fact too much of anything tends sooner or later to spoil home

surroundings. In this, as in all other connections, climatic and soil conditions frequently place some limitations upon the kind of things which one should plant, and it always pays to engage the services of an expert rather than a salesman, pure and simple.

A good deal of careful consideration should be given to the planting around the house foundation. A beautiful house in a fair landscape is the most delightful scene of the cultivated earth. The union between the house and the ground near it—a happy marriage it should be—is worthy of more thought than is generally given to it. If one does not care to carry out the landscape development of his entire property all at once, the first thing he should do is to tie the house to the grounds by suitable foundation planting. For all the year round effects such plants should invariably have evergreen foliage, and produce flowers and ornamental berries. While it is not absolutely necessary it is desirable that each species should be capable of exhibiting during the year all three of these features. It is extremely rare to find foundation plantings combining these characteristics, and far too many of them consist almost entirely of the most unsuitable subjects, such as Pine, Spruce, Fir, and other cheaper fast growing things which in a few years will have to be removed. It is in every way preferable to use dwarfed, slow growing plants of high quality which are less commonplace.

Without enumerating all of the better class plants which may be used in creating a perennially pleasing foundation planting, we would like to mention a few of the better and in some cases, the least known subjects.

For the background the upright *Cotoneaster simmonsii* is good, as it gives evergreen foliage, pretty flowers and bright red berries. *Ilex crenata*, Japanese Holly, is notable for its rich, glossy foliage and blue-black fruit. Another interesting plant for the back, but not so compact as the above, is *Viburnum rhytidophyllum*, Evergreen Snowball, its leaves are a rich green all the year round, the white flowers being followed by jet black berries. Having the same characteristics as its upright relative, the trailing *Cotoneaster microphylla* is very effective in front, and where anything low growing is desired the Japanese Yew, *Taxus cuspidata* is one of the best foundation plants from the point of view of its evergreen foliage alone. This does well both in shade as well as in full sun. While not absolutely evergreen, excepting in the South, *Abelia rupestris* is a valuable dwarf shrub, as its chaste, light pink, bell-shaped flowers are produced in great profusion from June until the advent of Winter.

For the quite shady side of the house that gem among our native Rhododendrons, *R. carolinianum*, should always have a place, and the well known Mountain Laurel, *Kalmia latifolia* with its pink and white flowers in June is also suitable. Among dwarfed subjects for a shady situation are the evergreen Azaleas, *Andromeda*, *Leucothoe*, Scotch Heather, together with its lovely flowers of intense fragrance, and *Daphne cneorum*.

Use should be made of the unique little ground cover plants like *Pachystima canbyi* and *Pachysandra terminalis*. Dotted about towards the foreground among taller things the Lily of the Valley and hardy double Violet are very effective. Pleasing use can also be made of Native Ferns.

A good deal of foundation planting is done by the use of the dwarfed and slow growing *Thuja*, *Retinospora*, *Biota* and *Buxus*, these do not, however, present so many interesting and pleasing features as plants like those previously mentioned as they are simply evergreens and when used exclusively become monotonous.

LOYALTY TO THE AMERICAN TRADE

THE severe frost that has recently been experienced in Holland, bringing disaster to a large percentage of the stock of Fall bulbs, will make it difficult to secure a sufficient supply of bulbs of the best quality. This calls strongly to mind the practice of so-called "representatives" of Holland growers who tour this country during the Spring and early Summer months, soliciting bulb orders, and who return to Holland in July when they buy up the remaining bulb stock of the Holland growers. The significant point is that they do not buy the bulbs until they have sold them in this country. In this way it is impossible for these so-called "representatives" to secure the best bulbs as they can purchase at that time only the stock that has been left over. This season with the bulb supply in Holland so greatly reduced, it will be necessary for them to buy up stock anywhere and everywhere in order to fill their orders. One need not over-exert one's imagination as to the quality of the bulbs they will be able to ship to America this Fall.

Reputable and dependable American importers of Holland bulbs buy the bulbs before selling them, contracting a year in advance with reliable Holland growers for their cultures. They thus make certain of securing only the best quality of bulbs for the American public. With the recent heavy damage to the stock of Fall bulbs these firms as well as the so-called "representatives" are going to find it no easy task to obtain bulbs sufficient to meet the demand. They can, however, be depended upon to import no bulbs of questionable quality, for the Holland growers from whom they secure their bulbs plan in advance to raise a crop of bulbs large enough to cover any possibility of loss by natural causes.

Another dangerous factor in purchasing bulbs from "representatives" of Holland growers lies in the transportation. Upon placing their orders with Holland growers they give instructions to ship the orders direct to the purchasers, for they provide no means of looking after the bulbs on their arrival in this country. As a general rule, fourteen to fifteen days are required from the time of leaving Holland to the arrival of the bulbs at the pier on this side. Here the transportation company more often than not puts the cases aside for a week or ten days. Then another three to four days, or more, are required to transport the bulbs to their final destination. With such a lapse of time the bulbs are quite likely to become blind, from being overheated in the cases, while the cases are lying on the pier in the warm September sun, the month when such bulbs are usually shipped to this country, and their productive value is thus entirely lost. It is not possible to detect that the bulbs have become blind after they have cooled again, so the purchaser on the receipt of the bulbs has no knowledge of this condition, nor does he gain this knowledge until the bulbs have been planted and failed to bloom.

Immediately upon their arrival at the piers, cases of bulbs which have been packed with care in Holland, imported by reliable American firms, are opened for examination. If there are any indications that the contents are overheated, the bulbs are cast aside so that there will be no risk of sending blind bulbs to customers. Every precaution is taken that the bulbs with which the orders of dependable American firms are filled, are in perfect condition. The American public should think twice before placing an order with a "representative" of a Holland grower and then should place it with an American firm whose reputation is well established.

Budded versus Own Root Roses

W. N. CRAIG

I AM always interested in my good friend Arthur Smith's articles appearing each month in the GARDENERS' CHRONICLE OF AMERICA and usually agree with what he says. I must, however take exception to some statements contained in his second article on "Roses and the Rose Garden" on page 113 and 114 of the April issue.

Mr. Smith states, "When a rose is upon its own roots it is less liable to Winter kill, for if it should be killed to the ground, it will invariably send up new growth from below." He further states, "Roses on their own roots are always more permanent than grafted ones," "there is always more dying out among grafted or budded roses in connection with the teas and their hybrids than own root ones." I cannot agree with any of the foregoing statements as my experience of 32 years in New England has amply proven that a very small number of own root roses are of any value in our climate, and that to achieve success with hardy roses it is absolutely necessary to use budded or grafted stock.

I can show Mr. Smith, or any own root enthusiasts, plants of such Hybrid Perpetuals as General Jacqueminot, Magna Charta, Mrs. Laing, Mrs. R. S. Sharman Crawford, Paul Neyron, John Hooper, Baron de Bonstetten, and Mme. Gabriel Luizet, which have stood 25 to 30 years of New England Winters where temperatures of 15 to 25 below zero are sometimes recorded, with nothing but soil protection, and all are plants worked on the *manetti* stock; and plants of Frau Karl Druschki, Gruss an Teplitz, Gloire de Dijon and Mme. Caroline Testout planted nearly as long, all worked on *manetti* or seedling briar stocks. I can take any sceptics to an old garden where there are Hybrid Perpetuals planted as much as 44 years ago and still hale and hearty, but I do not know of any one in our climate who has been able to keep own root roses alive more than two or three years with the possible exceptions of a few of the more vigorous ramblers and H. P.'s.

Budded or grafted roses have much greater vigor than own root roses, and prove far more Winter hardy. While it is true that there is some trouble with the suckers from the stocks, these possess much greater vigor than the roses themselves, are very thorny and carry 7 or more leaf petioles compared with 5 on the roses so that even an amateur can readily distinguish them.

If as Mr. Smith states, own root roses are so much the best why is it that such firms as Bobbink and Atkins work all their hardy roses on *multiflora* stock and this in Mr. Smith's own state? Whether *multiflora* will prove as good a stock as *manetti* time alone can tell. It has not proven successful for indoor roses and time is needed to prove its value outdoors.

A majority of amateurs and far too many professional gardeners plant roses too shallow, the union on budded or grafted plants should be covered fully three inches. When it is above the ground success cannot be attained.

For the warmest states own root roses are, I believe, the best, but I would earnestly warn any readers "in the more northern states" not to plant them under any consideration. In Great Britain where as fine hardy roses are grown as anywhere in the world, nearly all H. P.'s are worked on the *manetti*, and Hybrid Teas on the seedling briar. It is not possible even in that climate to have vigor, longevity and floriferousness, from own root roses.

Paul Neyron is Mr. Smith's choice as the best H. P. While a fine old rose carrying a very large but unsym-

metrical flower, I do not consider this in the same class as that finest of all white roses, Frau Karl Druschki. While that beautiful pink Mrs. John Laing owing to its persistent flowering qualities (which qualities Druschki also possesses) is also much superior.

Among climbing or pillar roses Mr. Smith does not mention the beautiful Tausendschön, not so vigorous as Dorothy Perkins (which he also ignores) but very reliable in New England and an early bloomer. Silver Moon, one of Dr. Van Fleet's charming introductions is the most beautiful white climber we have; it however, has some Cherokee blood in it and is a little more tender than others, but we find that by cutting this and other climbers loose just before the ground freezes up, laying them down and sprinkling a little soil over them, they winter successfully. We never cover any hardy roses with strawy manure as it makes an ideal meeting place for field mice, and the destruction caused by them each Winter is very serious.

While it is true that of late years the H. T.'s have largely usurped the older H. P.'s in popularity, owing to their more persistent flowering quantities, in the colder New England states the H. P.'s can only be successfully wintered out-doors. Where H. T.'s are grown, it is necessary to carry them over Winter in frames, in cold cellars, or by burying out-doors. Any one foolish enough to plant own root roses in these States will not have to wait more than one year to learn of their mistake.

FLOWERS AS TEACHERS

(Continued from page 145)

*One of them holds a flower
Under the other's chin;
The big hats shade their faces
From the sunshine stealing in.*

*The buttercup's bright reflection,
A dapple of golden hue,
And the smiling lips repeating
"I like butter; do you?"*

Genie L. and Florence J. Boyce.

The dainty, fragrant Trailing Arbutus is supposed to imply "welcome," and can anyone familiar with the tradition that this beautiful, brave flower, the first to greet the self-sacrificing Pilgrims after their Winter of hardship and misfortune, doubt it was a welcome sight and bought to their sad hearts a renewal of hope and, as Whittier tells us in his poem "The Mayflowers," a promise that

*"Warmer suns ere long shall bring
To life the frozen sod;
And, through the dead leaves of hope, shall spring
Afresh the flowers of God."*

Bronx Park, N. Y.

Work for the Month in the Garden

SAMUEL GOLDING

BY this date, around the middle of May, it can generally be regarded as safe to plant outside the more hardy plants that have been raised in the greenhouse and frames. Their capacity is always over-taxed during the early May days and any opportunity to relieve the congestion is welcome. The recent severe frosts and cold winds remind us that some precaution is necessary, that it often pays best to go slowly, and that, if we take early chances, we have a reserve supply on hand. One must be careful to see that the stock is thoroughly hardened before planting out into its permanent quarters. Always utilize the most sheltered and sunny borders for early crops.

If showery and warm weather prevails, the growth of the early sown seeds becomes more apparent each day. Peas should be staked early to keep them growing erect. Keep up successions of late peas until the end of the month. After that time peas cannot be regarded as a paying crop to plant in most localities. Sweet corn and lima beans take the place of peas, when their usefulness is past.

Plant out tomatoes, sweet corn, squash, and all of the more hardy vegetables raised in frames, but it is wise to defer the planting out of egg plant and the more tender sorts until the ground is warm.

Sow bush limas, melons, cucumbers, squash, okra, etc., and pole limas, if climatic conditions permit. There is nothing gained in hurrying on with the planting of this crop of the soil is wet and cold. Sow string beans at frequent intervals; also carrots, beets, and salads. The cultivator should be kept active between the rows of these crops when growing.

Plant out the early celery and transplant the latter seedlings into well prepared soil to encourage good root action, which is an asset when they are set into their growing quarters.

Cut over the asparagus beds daily, removing all weak and deformed growths, which tend to exhaust the crown; to no useful purpose. Give the beds a dressing of super phosphate, or other approved fertilizer.

Mulch the strawberry plantations with clean straw before the fruit is far advanced, which prevents damage from heavy rains, and contact with the soil.

All varieties of annuals can now be sown outside for late blooming. Those which were sown previously will require transplanting, and will soon make splendid plants to take the place of the Spring blooming species. Some of the most hardy, and those raised in frames for early cut flowers, can be planted out where they are to bloom. Among such are candytuft, larkspurs, annual phlox, antirrhinums, verbenas, stocks, asters, which will be safe if planted where they can secure protection if necessary.

The flower gardens will be a blaze of color during the first weeks of May, as the cold weather of April retarded many plants which usually bloom during the last weeks of that month. Flowering shrubs and spring flowers at this time make a display unsurpassed during the whole year. Darwin and other May flowering tulips supply the main feature in the beds, their great range of colors being admirably adapted for color schemes in which the Breeders are a wonderful asset. At this season it is an excellent plan to make notes for future reference as to the outstand-

ing merit of any particular varieties and their qualities for our special purposes.

Disbud poodles if fine individual blooms are desired. If the weather is dry and the soil light, a good manual watering will assist them when their buds are swelling. These plants have a deservedly wide and ever growing popularity, their varied forms and colors make them second to none as a cut flower for home decoration and an embellishment for the garden.

Plant out *Hyacinthus candicans* and *gladioli*. As sweet peas are growing rapidly, it is necessary that they be well staked, or if trained on netting, they should be tied up frequently.

Keep an eye on rose bushes, watching out for the small caterpillar which destroys the young growth and buds. It is easily detected as it rolls up the leaves and hides in the center, where it can be dealt with. Spray early aphid and mildew on these bushes.

Delphiniums, campanulas, hollyhocks, and other early Summer flowering plants should be staked before they have grown too tall and can be easily ruined by sudden heavy rains and winds.

Cut back flowering shrubs after they have passed out of bloom, and see that newly planted shrubs and trees do not suffer from drought. When watering them, do it thoroughly.

JUNE

All parts of the vegetable garden will now have their full quota of growing crops, and one of the most important tasks will be the thinning out of young seedlings as soon as they are large enough to handle. It is obvious that this should be done early so that the plants to be raised will not be drawn or spindly from being too crowded at the early stages. It is equally as important with plants grown outside as with those grown under glass that they have plenty of room for development to encourage stocks and sturdy plants.

The hoe and cultivator should always play an important part in the garden during this month; frequent and deep soil stirring must be the order of the day. Not only does this conserve the moisture in the soil, but it keeps down weeds which are very persistent throughout June, and especially so, after warm rains. Artificial watering will have to be resorted to and when necessary, give it thoroughly. If watered sparingly, the plants are more injured than otherwise as the first hour's sunshine dries it up, leaving only a baked surface.

To fight the various pests which will now trouble us from time to time requires our diligent watching and constant attention. Spray for fungoid and insects; caterpillars, cut worms, rose bugs, potato bugs are among those to be combated. The gardeners of today are fortunate in having so many good antidotes to keep these enemies in check.

To drive off potato bugs which appear on warm, sunny days, cultivate well between the potato hills and spray. Paris Green is effective if flea beetle is prevalent. Dust the plants over in the mornings when the dew is still on them, with lime and soot. It is a persistent insect and often demands strong measures to get rid of it.

The Greenhouse, Month to Month

GEORGE F. STEWART

THE last half of May and the first part of June is in all probability about as trying a time for the greenhouse man as any part of the year. At this season, the weather is quite changeable, especially along the New England coast. The east winds are proverbial in the region mentioned and one has to be watchful to avoid draughts. The greenhouses may not have an ideal location and ventilation may not be all that one desires to give the proper amount of air without being draughty. My opinion is that the last word has not been said, by greenhouse architects, about the proper mode of ventilation, for these structures in a variable climate such as the above. A greenhouse man who in early life has developed a gift for careful watering and ventilating, is a greater prize than an expert on composts, and when saying this, I do not belittle a knowledge of soils. I know that with many it takes years of experience to know at a glance when a plant needs water, or when stepping in at the door of a given compartment to know if the temperature is right; so let the older men have patience with youth if the love of plants is there.

Cool house hard wood plants that were potted after flowering last month will now have a good grip on the new compost, and may be pruned into shape for another year. Cut the shoots near the top of the plants well back. The growth on the sides and lower down will not be so strong, and only the strongest will need shortening. Later on these plants will need looking over and some of the stronger breaks should be pinched again before they are allowed to get too long.

The camellias are growing freely except perhaps some of the very late flowering varieties. A sprinkling of Clay's fertilizer, soot, and weak cow manure water we have found beneficial for them. Applications once a week alternately are enough, being sure that they are watered with clean water two or three times between doses. This may be kept up until the flower buds begin to swell. Insects such as scale and mealy bug are often found on camellias, but may never be seen if weekly syringings with some standard insecticide such as Aphine is given. This also applies to acacias and other hard wood plants that are attacked by any of these pests.

Do not forget to have batches of *Stevia* started for Fall use. Cuttings root readily and we find it best to grow them along in pots. The tall form is known as *S. serrata*, having a dwarf form, var. *nana*. Botanists, however, tell us that the proper name is *Piqueria trinervia*. I have always found it best to grow both the tall and dwarf forms as they both have a place in decorative work.

Calceolarias intended for exhibition in the early part of May should now be staked out. Keep them as cool as possible and shaded from strong sunshine. By pinching, the *Stewartii* type may be had as late as July. We allow about seven weeks from date of pinching until the time they are wanted to flower, at this season of the year.

We have *Boronia* and *Pimelia* flowering just now. Any that need a shift after flowering may be potted in a compost as advised last month for acacias and *Eriostemon*. After they grip the new soil, cut them back about half way between the flower and the place they were cut back the preceding year. *Pimelias* are handsome plants and should be more grown. They may be flowered in small

pots or grown on into larger specimens which will be admired by every plant lover. Syringe them well every few days, as red spider has a great liking for them. Do not forget to fumigate about every nine or ten days in the cool house.

In the tropical house, any *Anthuriums*, such as *andraeanum*, that have been mossed with sphagnum, because they were getting too leggy, will now have rooted well into it and may be cut over and potted into suitable receptacles. The old stump will break and furnish more plants if desired later on.

Croton, or to be more modern, *Codiaeum*, cuttings that were rooted earlier in the year, should soon be ready for six-inch pots which will be a large enough size for the first year. I believe that they go through the short days better if they are well pot bound by Fall. Keep them well up to the glass and have a light shade over them until the end of September. A good fibrous loam with some sand and charcoal added to keep sweet and porous, is a fine potting medium. Some sheep manure and bone meal may also be added. Watch carefully for bug scale and red spider.

Fancy leaved caladiums are very useful plants to fill up any room that may be vacant during the Summer. Three tubers to an eight-inch pot can be grown into a nice plant. Pot in a fairly rich loam with a moderate quality of sand added. Soft coal soot will also help to bring out the right coloring. A bench that can be lightly shaded is what they require as regards light. Avoid bottom air.

Ixoras are pleasing Summer flowering plants and if grown in good loam and not over potted, will flower freely. A plant or two of *Medinilla* will also always attract attention when in flower. The varieties *amabilis* and *magnifica superba* are very striking.

Among twining tropical shrubs that flower freely are *Allamandas*: and *Clerodendrons*, which can be had in flower from the last of March until October by ripening the wood by drying off after a good growth is made. *Dipladenias* begin flowering in June and will last until Christmas. Though classed as tropical plants, these twining shrubs will grow better and give more flower in a lighter and more airy house than the majority of stove plants. Spray all these plants when not in flower on all bright days with clean water, but unless there is a good deal of heat in the pipes during the night. I believe it is more advisable to have the foliage dry over night.

Dendrobium nobile, *D. phalaenopsis*, and others will now be showing their young growths, and great care in watering must be taken to avoid damping off of the young shoots. Dipping in a tank of water, keeping the water away from where the young growths are, I find the safest method at this stage, and until the roots are seen to be developing from the young shoot when the hose may again be used, and syringing practiced in the early part of bright days. *Oncidium*s also need to be watched for the same trouble with their young growths. What are known as intermediate house orchids should not receive abundance of air on all warm days, and from now on a little over night, according to the weather. When the thermometer goes above 70 degrees out doors, as it will now often do, I have never observed that plenty of fresh

air harmed any plant, provided the plant becomes accustomed to it. Plants of all kinds can, I believe, suffer from lack of fresh air as well as human beings and many of them can stand a lower temperature than the one in which collectors tell us they found them growing in out doors. The illustration on this page is a case in point: a plant of *Croton Baronne de Rothschild*, about twenty years old, whose treatment during all that time I have been familiar with. It has been used as a veranda plant from the time it was six years old, from the middle of June until the middle of September every year. Its position has been on the end of a veranda without any cov-

Croton Baronne de Rothschild.

ering overhead, no protection whatever, and facing due north. The photo was taken in September when the color was excellent, and the foliage, as can be seen in the picture, was well furnished. The plant has always been wintered in a palm house where the thermometer stood about 55 degrees, and has never been coddled during its life in a hot, humid atmosphere. Every Fall when it is to be housed, the points are nipped out of all the strong shoots. This has taken place six miles north of Boston.

The work in the grape house hereafter will largely be routine; pinching main shoots and laterals; tying and thinning grapes, according to the stage of advancement of the crop. Do not over crop the vines which is more often the tendency, owing, I suppose, to the large amount of surplus bunches that come on a vine. It is hard to advise in this matter when one does not know all the conditions; everyone must learn by experience. In a span roof house, twenty-five feet wide, it is better to be well under thirty pounds to the rod. It takes an expert grape grower to crop a vine to the limit and to come out safely, leaving his canes in good condition for another year. Houses that are taking on their blooms require abundance of air, top and bottom, on mild days, and should have a free circulation over night. If properly watered when they show signs of coloring, they should ripen their crop without any more.

Early peaches and nectarines will now be ripening and may be given plenty of air on all favorable occasions. Careful watering must be practiced or the flavor of the

fruit will be affected. On later trees see that the shoots do not overcrowd the trellis and remove all weak surplus growths.

Melons may be grown in any empty greenhouse that has been used for bedding plants. Sow seeds in small pots. Make little hills of good rich loam on the bench, fifteen to eighteen inches apart. More loam can be added as they grow. Train to one shoot, and set about three fruits to the plant. Blooms must be hand fertilized to make sure of a set all at the same time, so that the fruits on each vine will all swell together.

If not fruit is grown, be careful that the trees do not suffer from lack of water. The plants are always grown in the smallest receptacle possible, and must be liberally fed with standard fruit manures. It is better to use variety in stimulants but do not overdo. The directions given by manufacturers are as a rule reliable. Of course, I would not discourage individual experimentation in this line, as much valuable experience is gained thereby. Isolate a few plants, say an apple, a pear, and a peach tree, etc., and try them out, but on no account risk your entire crop. Syringe the trees well on all bright days until the fruit approaches the ripening period.

When the fruit is gathered, give them a thorough spraying and by the end of June they may be set out doors to ripen the wood for next season. Have them always near water, as they will require attention several times a day.

Keep a note book, and make original observations, as plant growth is a wide field to work on, especially under artificial conditions. Keep your ears open for hints from others, for sometimes a very poor grower will drop useful information which he himself may not be able to put into practice. Emerson learned much from his everyday acquaintances, and his strong point was the faculty of expressing what he saw and heard, mostly among his Concord friends.

WORK FOR THE MONTH IN THE GARDEN

(Continued from page 155)

If the okra does not appear to be coming up well, look over the rows carefully as one often finds that they have been eaten off by cut worms, just as they are breaking through the soil. Poison bait is generally effective in combatting these insects, but a more certain method for the small garden is to look over each plant and destroy any cut worms that may be found.

The completion of the Summer bedding will be the object in view as all are eager to get the plants in the ground and well established before the very hot weather comes. Plants taken up from the Spring beds which are to be propagated and grown on again, should be laid in at once in a shady place until they can be properly cared for. All tulips which must be removed should be lifted with care and heeled in the soil in a half shady place to ripen off the bulbs before storing.

Plant out cannas and dahlias. It is a good plan to place the stakes, or other means of support, at the time of planting, for if this is done when the plant is growing vigorously, the tubers and roots may be injured. Plant another batch of *Gladioli*, which can be relied upon to make a display towards the end of September.

Build thee more stately mansions, O my soul,
As the swift seasons roll!
Leave they low, vaulted past!
Let each new temple, nobler than the last,
Shut thee from heaven, with a dome more vast,
Till thou at last art free,
Leaving thine outgrown shell by life's unresting sea.
—O. W. Holmes.

ANNUALS IN GARDEN DECORATION

The Treatment and Conditions Suitable for the Different Kinds

TO the older enthusiast in gardening it has long been common knowledge that in annuals we have long harbored angels unaware, for what we do in the greenhouse, as a matter of course, with a few pots of *Clarkia*, *Godetia*, *Schizanthus*, *Viscaria* and Sweet Peas can be as readily reproduced in the open garden on a larger scale, the main difficulty being to convince ourselves that the thing is worth doing. Let us, however, concede that the methodical and conscientious care we expend yearly in raising China Asters, Antirrhinums and Stocks can be extended to cover the whole family of annuals, then the result will be an enormous gain to the garden both esthetically and practically, and for ourselves an addition to our plant knowledge that will agreeably surprise us in the breadth of outlook that it entails.

In the decorative scheme of the garden the greatest success follows when distinctive positions are chosen and always with due regard to the plants' requirements. Gourds are important fast-growing annuals for clothing trellis-work and lightly constructed pergolas, and require rich, light soil in a sunny position. Sweet Peas are ubiquitous, but are best displayed in clumps, using bushy sticks or wire supports for them to cling to. *Ipomœa imperialis*, also a climber, will succeed in ordinary garden soil, while *Tropœolum majus* and *canariense*, though grateful for some slight preparation, will, however, often give wonderful results in very indifferent soil; like Sweet Peas, the two last-named display themselves to advantage over bushy sticks or any light, wire trellis-work.

A section of annuals that luxuriates in hot positions, where the soil is rather poor in quality and not likely to become oversaturated with rain, includes *Dimorphotheca*, *Eschscholtzia* (biennial, but always most satisfactory when grown as an annual), *Linaria alpina* (perennial), *Calceolaria mexicana*, *Portulacas* and *Nemophila insignis*. Then there are two annuals that ask for quite different conditions: the diminutive *Ionopsidium acule* prefers slight moisture in the soil and enjoys some shade during the hottest part of the day; while the other, *Limnanthes Douglasii*, is an annual that revels in cool, moist conditions at the root, with the vegetative part luxuriating in sunshine.

Annuals of gigantic stature are found in *Cannabis gigantea* and the various forms of *Helianthus annuus*, the first named having its attraction in the foliage. When employed together an excellent screen will quickly result, while the effect in late Summer of the big Sunflowers standing boldly out from a mass of greenery presents quite a pleasing feature in the garden.

The annuals, however, which give the greatest service in the garden are those I define as border annuals; they are strictly hardy annuals and should be sown where they will flower, March being one of the best months to begin. I have made two groups; the first, embracing the tallest sorts, includes *Calliopsis*, *Centaurea*, *Clarkia*, *Delphinium* (Larkspur), *Godetia*, *Helianthus*, *Lavatera* and *Papaver*. The second group, being dwarfier, will require placing in front of those previous named, and embraces *Asperula*, *Bartonia*, *Calendula*, *Calliopsis*, *Godetia* (dwarf sorts), *Gypsophila elegans*, *Iberis umbellata*, *Linaria reticulata*, *Malcomia* (Virginia Stock), *Nigella*, *Phacelia*, *Reseda* and *Viscaria*.

Whether annuals are sown in straight rows or clumps of irregular shape is immaterial, as with a little foresight, even when sown in straight rows in the first instance, it is tolerably easy to give the groups a broken or intergrouping effect, although, of course, the clump method is much more practical when this end is in view. The great point leading to success lies in thinning out the plants early and systematically; that is, in two or three operations; ultimately the plants should stand as far apart as half their average height. Then, as soon as the final thinning is complete, insert a few dwarf, bushy boughs among the plants, so that when in flower no evidence of this support may be seen.

With regard to the soil for annuals, this should be deeply dug and moderately enriched with farmyard manure to which a dressing of slaked lime should be given in advance of sowing. Ground freely tamped just previous to sowing, is best dressed with steamed bone flour instead of lime, this being lightly pricked into the surface with a fork, using it at the rate of 1½ pound per rod of ground.

MULCHING NEWLY PLANTED FRUIT TREES

SO much depends upon the start that a young fruit tree makes the first year of planting that every care should be taken to secure its growth. In doing so, be sure that newly planted

trees get enough, and oftentimes more than enough, of moisture at the roots, but seasons are uncertain, and sometimes we get a hot, dry Summer. Trees planted in the Autumn, and which before Winter set in have got good hold of the soil, are not so likely to suffer, but where planting was deferred until Spring some means should be taken to protect the roots. With all the care that may be bestowed upon them in the way of watering, progress will never be so good and the trees will never exhibit that thrifty vigor as when the soil around the roots is preserved in a more or less uniformly moist state. By the middle of March a good coat of litter, some 4 inches thick, should be applied, for the drying winds of early Spring are apt to unduly parch the soil before watering is thought of. Watering, indeed, in the case of newly planted trees must be considered as a necessary evil, to be avoided if possible, for if the roots can be kept cool and moist without drenching them with cold water, so much the better for the trees, the health of which in a great measure depends upon the soil in which they are planted remaining at a more or less even temperature.

With a good mulch of long manure, or some such non-conducting material, there will be but little need to water until the Summer arrives, and then an occasional soaking, if the weather should prove exceptionally dry, will ensure to the roots the necessary amount of moisture, any deficiency of which during the first year of growth will exercise a most prejudicial effect upon the future welfare of the tree. In Normandy and in other parts of the Continent, where all that relates to the apple is regarded as of the highest interest, mulching is considered one of the most important operations connected with the planting of fruit trees. Few planters there would consider that they had carried out the work in a thorough and workmanlike manner did they omit covering the soil over the roots with a thick layer of non-conducting material. Mulching not only acts beneficially in preserving the tree against the effects of the sun's scorching rays, but it lessens labor to a considerable extent, and where the trees are set upon slightly raised mounds it must be regarded as an absolute necessity. Drought is by no means the only enemy that fresh-planted trees have to contend with, as hard frost and continued easterly winds, drying out the soil and arresting the flow of sap, exercise an equally inimical effect upon their health. In many cases where new plantations have failed to do well the cause might be traced to the effects of a hard Winter. When a severe Winter is succeeded by a harsh, dry, early Spring, newly planted trees are apt to get their vitality so lowered that no amount of care afterwards will restore the lost vital energy.—*Gardening Illustrated*.

THE PRINCIPLES OF VEGETABLE GARDENING, by L. H. Bailey; eighteenth edition; re-made and re-set. The Macmillan Company, New York.

A few sentences from the concluding paragraph deepen and impress the almost tender feelings with which has been examined this work of a man great in many fields of horticulture and yet careful, accurate, thoughtful and thorough in what might be regarded by some as a rather humble field for his genius.

"Here ends the vegetable-gardening book. As it begins with plants, so it ends with the home; thereby is the personal and human interest of the book emphasized. The author enjoyed writing the book twenty years ago. Still more has he enjoyed re-writing it in his maturer years, and he has lived the subject all over again. He has had many aids not available then, for now there are numerous workers. . . . He has tried to make it sound, but can not hope to have escaped errors: the reader must exercise his own judgment in the use of statements and advice. The author does not expect to re-write the book again; and if subsequent editions are needed, certain changes may be made."

It would be bold to attempt a criticism in any way; the two slight misprints discovered are not worth mentioning. Space would better be given, and can well be given, to the author's own outline of the plan of the book.

"After the introductory chapter, defining the subject-field, the different vegetables are taken up in groups. They are discussed in groups so that related crops may be considered together, avoiding considerable repetition of advice and contributing to a clearer understanding of the subject. . . . The main principles or considerations are printed in italic type at the beginning. Then follows in small type the information that should be available for ready reference, as distances at which plants are to stand, quantity

of seed or number of plants to the acre, time of sowing or planting, yields, together with very brief statements of the most important diseases and insects. The condensed paragraphs on the maladies and pests are prepared especially for this edition of the book, all on a uniform pattern.

The treatment just outlined, occupies about two-thirds of this compactly and neatly made volume of nearly 500 pages; the last third is given up to an exceedingly valuable and up-to-date presentation of Glass, the Land and Its Treatment, Vegetable-gardening Tools and Implements; Seeds and Seedage, Other Management of the Vegetable-Garden, Marketing, Storing, Drying and the Home Garden.

NUT GROWING, by Robert T. Morris, M. D. The Macmillan Company, New York.

Several considerations make this well-written volume one of the most valuable works that have appeared in the field of horticulture in a long time. As it points out, nut trees of many kinds can supply all the protein, oils and vitamins belonging to the meat group of foods. But it is questionable if the author is warranted in declaring, as he does, that "were wheat, corn, and rice and other grains to be suddenly stricken from the earth, man might live better than ever before," for nuts are a very concentrated food, not absorbed by weak digestions and always best eaten with a bulkier food made from grains or vegetables, salted crackers being one of the superior concomitants. Hence the doctor's remarks concerning the part that nuts should play in allaying the fears of those who believe that the world is in danger of becoming over-populated are themselves to be "taken with a grain of salt." Yet his discussion of the Malthusian doctrine and of various checks to over-population is interesting and embraces reflections that economists would do well to ponder over more than they do.

That it is true that much land now waste could be made very productive is suggested by Doctor Morris' affirming that in the state of his residence, Connecticut, nearly half the land is not tilled and yet ought to bear nuts of more value than the food grown upon the land now tilled, while over the country generally much swampy land, some of which is drained at great expense, could be made to yield edible nuts from various water plants. The market value of nuts already grown commercially in this country has mounted to enormous figures. Of the over \$57,000,000 paid for importations, a large part could be kept in this country, while it is true also that as nuts become more appreciated, the kinds that cannot be grown in this country will undoubtedly be brought in in larger quantities. Nuts are being more and more appreciated and more trees are annually being planted even to serve partly as shade or ornament; for one thing, because they root so deeply, they permit the planting of undergrowth in landscape adornment as do not the shade and ornamental trees that are planted commonly. One particular tree, the Lancaster Heart Nut, introduced by J. F. Jones, of Lancaster, Pennsylvania, of robust growth, has "very large, almost tropical-looking foliage and quickly makes a striking and very beautiful specimen on the lawn or in the home grounds."

To meet the rapidly increasing demand many nurserymen have been supplying seeding trees, against which the book advises that they are greatly inferior to those propagated by grafts from trees of known excellence. For grafting is advocated a new method. It consists in covering the entire scion, as well as the wound in the stock, with melted paraffine, hardened slightly, if need be, with stearic acid. The theory is that while black or brown or amber wax halts the actinic rays of light, which promote the activity of bud chlorophyll, the paraffine allows the actinic rays to act upon the chlorophyll in the bud and in the bark of the scion and does not attract the destructive heat rays; it thus further, by covering the scion completely and shutting out the air, maintains sap tension equally throughout the fluctuations of negative and positive pressure caused by changes in light and temperature, prevents evaporation of the scion and prevents suberization; that is, the natural spread of a corky layer over the wound surface between the stock and the scion, and which forms a mechanical obstacle to union. This new method permits of *immediate* grafting,—the cutting of a scion directly from one tree and placing it at once upon another tree at almost any time during the Summer. But one of the most successful nut tree propagators regards Summer grafting as commercially impracticable and declares that one usually cannot get growth, and if one does get growth it does not mature. He still prefers also to use a heavy black wax, which trial has convinced him equals the paraffine, and even secures a covering that is better and takes half the time to apply. His men do better jobs with the dark wax, for when they use paraffine they cannot easily see when all the cuts are covered. The wax, furthermore, stays on from one year to the next, regardless of the weather.

A more questionable point in the book is the advocacy of severe pruning of the roots in transplanting. The grower just referred to strongly recommends, after extensive experimentation, that while the tops should be cut back almost mercilessly, the root system should be kept as nearly entire as possible.

One important matter omitted is a discussion of the handling of the nuts when they are gathered, for the quality is greatly improved by proper curing. All nuts should have the husks removed as soon as they are gathered and they should then be promptly dried out, for the tannin in the husks darkens the pellicle of the kernel and affects its taste.

Attention might have been called to the fact, also, that in cold climates nut trees often fail, not because of their not being hardy, but because of an aphid feeding upon the leaves, from which it passes to the twigs. The twigs then become pithy and are easily killed back in Winter. The Persian, or so-called English walnut, notably suffers in this way, while certain strains of it kept in health are hardy even as far north as southeastern Canada, not, however, in Minnesota, northern Iowa, Dakota and Wisconsin. But the book contains a complete and satisfactory treatment of the different kinds of nuts and directs in the obtaining of detailed information, also. It concludes with twenty-nine carefully executed drawings illustrating the processes of grafting.—F. B. M.

TRULY RURAL, by Richardson Wright. Houghton Mifflin Company, Boston.

The publishers' own commendation of this entertaining little book is perfectly just: "A man and his wife (a most charming man, with a delightful wife) buy an old country house and undertake its rejuvenation. There are chapters about the fine art of breakfasting and rearranging of closets, lovely interior vistas of an old colonial stairway or a perfect dining-room, or outside orchards and radiant gardens. There are many suggestions in this little book which will be of value for all who love houses and gardens, and much valuable information. And all readers, with a grain of the proud householder in their blood, will ache at least to rearrange their furniture or go out in the garden and dig."

The qualities that make Mr. Wright, who, by the way, is the editor of *House and Garden*, a "charming man," are those that have made so perennially charming the old Roman Horace,—genial and philosophic contentment and a vein of playful sarcasm that helps people, in spite of their shamming, whether voluntarily assumed or forced upon them, to find the verities of life. His chapter on Annuals, racy and yet properly appreciative, blandly declares that "American landscaping suffers at present from a serious attack of Naturalizitis. Wild gardening and massed shrubbery and tree-moving are its present-day passions. Its ideal is to hedge in the view and make one thing blend into another. Because of this the herbaceous border has lost some of its professional popularity and the annual garden is looked upon as the vagary of an unknowing mind." Some people, he declares, "make a garden because it is the fashionable thing to do; other people take gardening the way they would take a narcotic (the way some men take work)—to make themselves forget the bitter realities of life—still others make gardens because it is part of a full life." These last are the successful gardeners, the born gardeners, whom the author sympathetically analyses.—F. B. M.

THE APPLE TREE, by Liberty Hyde Bailey. The Macmillan Company, New York.

It is to be hoped that the booklets to follow in the series introduced by this one will succeed as well as does this in the aim of being *genial*. But it has other merits besides that of being perfectly adapted to promote a friendly feeling toward the apple tree. That it has a mission along this line is evident from the fact that in this country, despite all the urging to plant trees, the number of trees bearing this most healthful fruit has decreased, within the past ten years, in seven of the leading apple-growing states, from 65,200,000 to only 37,100,000.

The little book is delightful reading. It comes near being an idyl; in parts it is actually poetical, and in one place, extolling the fruit, it is almost lyrical. It is scholarly,—no work bearing the name of Professor Bailey could be otherwise. It skillfully contrives to impart, along with interesting history, narrative and delightful description, all within its small compass, fairly complete instructions for planting and caring for the trees also. The chapter devoted to The Dwarf Apple-Tree, though brief, is particularly commendable for its telling so plainly the truth about a subject too little understood by perhaps the majority of gardeners and owners of homes. How many, for example, know that the apple, more than any other fruit tree, roots from the scion if this is in contact with the earth and that for this reason the dwarf apple tree must not be set with the union beneath the surface of the ground?

It is not intended to be a handbook for the commercial grower. In accomplishing the purpose for which it is intended it seems to come a trifle short only in the list of varieties recommended for different parts of the country. This list is far from being up to date, as Professor Bailey himself remarks.—F. B. M.

LOCAL BRANCHES

Newport, R. I.: Andrew L. Dorward, chairman; Frederic Carter, secretary.

St. Louis, Mo.: George H. Pring, chairman; Hugo M. Schaff, secretary.

Nassau County, L. I.: John T. Everett, Glen Cove, chairman; John McCulloch, Oyster Bay, L. I., secretary.

Boston, Mass.: Robert Cameron, chairman.

SUSTAINING MEMBERS

William Boyce Thompson, Yonkers, N. Y. (Andrew Strachan, gardener), and Henry Penn, Boston, Mass., have become sustaining members of the association.

NEW MEMBERS

The following new members have recently been added to the membership of the association: John E. Connolly, Mt. Kisco, N. Y.; James Kelly, Glen Cove, L. I.; Ralph W. Caverly, West Somerville, Mass.; James Scott, Manchester, Mass.; Charles W. Philpott, Newport, R. I.; James Mulholland, New York, N. Y.

AMONG THE GARDENERS

George J. Oller recently resigned his position as superintendent of the Spencer Penrose estate, Broadmoor, Colorado Springs, Colo., accepted the position of superintendent on the estate of Mrs. Alexander Laughlin, Jr., Sewickley, Pa.

George J. Oller secured the position of gardener to Hamilton Kean, Elberon, N. J.

Peter Morrison accepted the position of gardener to Mrs. Otterley, Glen Cove, L. I.

Jack Baxter, who recently resigned his position as superintendent of Glen Echo Country Club, Normandy, Mo., has accepted the position of greenskeeper of the Dixmore Country Club, Homewood, Ill.

John G. Walker accepted the position of manager of the estate of Spencer Kellogg, Derby, N. Y.

1922 CONVENTION COMMITTEES

Plans are now under way for the 1922 convention to be held in Boston, September 12 to 15, and President Cameron has named the following committees:

Banquet and Entertainment Committee: Andrew Rogers, Chairman, James Methven, William Downs, Stewart A. Forbes, Henry Stewart, A. P. Dewar, L. B. Whyte, Gordon P. Stewart, John G. Duguid, William Till, Percival C. Veinot, James Donald.

Program Committee: Patrick W. Burke, Chairman, W. D. Nicholson, John Morris, W. D. Coutts, Thomas H. Westwood, Peter Arnott, Donald McKenzie.

Ladies' Reception Committee: Mrs. Hammond B. Tracy, Chairman, Mrs. W. N. Craig, Mrs. Wm. Anderson, Mrs. George Stewart, Mrs. Duncan Finlayson, Mrs. Andrew Rogers.

Finance Committee: William Kennedy, Chairman, Frank Murray, Peter Miller, Wm. Anderson, George F. Stewart, Eric Witterlow, Herbert W. Clarke, Wm. R. Thornhill, John L. Russell.

Transportation Committee: Walter H. Golby, Chairman, Julius Heurlin, Duncan Finlayson, Alfred E. Parsons, Wm. C. Rust, James Marlborough, B. Hammond Tracy, James Wheeler.

Publicity Committee: William N. Craig, Chairman, Gustave Thommen, E. J. Farrington.

William N. Craig is General Chairman of all local convention committees.

ON TRAINING YOUNG MEN

Considerable publicity has been given to the movement of training young men for the profession of gardening by a proposed course to be established at the Massachusetts Agricultural College through cooperation of the college authorities and the National Association of Gardeners.

On April 18 before the members of the Florists' and Gardeners' Club of Boston, Prof. Thayer of the Massachusetts Agricultural College stated that the college is hopeful of starting a special two-year course for training gardeners, next Fall, the plan to provide for six months of school work after which the boys will be sent to private places for practical experience to be followed by a final year's study at the college, when they will be sent out for a year's apprenticeship under the national association. Keen interest was aroused in Prof. Thayer's statement which led to a splendid editorial on "College Trained Gardeners" in the April 25 issue of Horticulture, which condensed, is as follows:

For many years both the trade and private gardeners contended that the only way to become a skilled florist or gardener was to start at the bottom and work up. It is now being realized that a boy who has the theory of horticulture on which to lay his practical work can advance more quickly and make himself more capable and in the end become a more capable gardener or florist, than the boy who has not had these advantages. It has also been contended that college boys think so highly of themselves that they are not willing to take a humble position upon graduation. At a recent horticultural meeting at Boston, W. N. Craig said that he had employed several boys from colleges and had found them ready to do any work required of them, manifesting eagerness to learn all they could about the operation of a private estate.

Prof. Thayer said that college work was expected to be only preparatory and that practical experience is necessary to fit a graduate for an advanced position, and that the students realized this fact and accepted it. As the country lacks the apprenticeship system which prevails across the water and which keeps a new supply of gardeners coming on every year, the course at the college and the practical training under the supervision of the National Association of Gardeners will step into the breach and remedy this difficulty. The association is largely held responsible for this movement.

It's Never Too Late!

Your most cherished wishes for an old-fashioned Hardy Garden or Rockery may be gratified. You can start any time with our well-established, ready-to-bloom plants.

Palisades Pot-Grown Perennials to Start that Rockery or Handy Border NOW

Within three or four weeks after setting out plants you may enjoy the companionship of a pretty little rock garden. Take your choice of these, according to your space and garden situation:

- 12 Hardy Rock Plants for Sunny or Shady Border or Rockery in 12 Varieties for \$2.00
- 25 Hardy Rock Plants for Sunny or Shady Border or Rockery in 12 Varieties for..... \$4.00
- 50 Hardy Rock Plants for Sunny or Shady Border or Rockery in 25 Varieties for \$7.50

You will find it to abound with offers of plant material particularly suitable for hardy borders, rock gardens and old-fashioned gardens. Our special endeavors are to provide a complete assortment, hence, whether you want the old stand-bys or the new things of merit, we believe we can serve you. Please write for our free catalogue and mention G. C.

PALISADES NURSERIES, Inc.
SPARKILL, NEW YORK

LOCAL SOCIETIES

THE CLEVELAND HORT. SOCIETY

The regular monthly meeting was held April 9, with Mr. Brydon in the chair. The usual business was transacted, three new members being elected.

The exhibits of the evening were exceptionally fine, Mr. Francis being awarded a certificate of merit on eight vases of sweet peas which he had grown for W. A. Burpee & Co. The colors ranged in white, pinks, and lavenders, with stems on an average of twenty inches, carrying three and four large and beautiful flowers, far superior to the old winter flowering varieties. The varieties exhibited were Early Lemon Beauty, Early Fire King, Mrs. Kerr, Early Pink Beauty, Early Loveliness, Early Fairy Queen, Early Exquisite, Early Rosebud, Early Bluejacket, and Early Daintiness.

Mr. Francis explained his manner of cultivation to the members, informing them the beds were dug about eighteen inches deep and mixed with well-rotted manure and bone meal. The plants were thinned to six inches apart and run to single stems, all lateral growths being pinched out. The seed was sown in October, 1921, and grown cool.

Mr. Broadfield exhibited *Antirrhinum*, White Giant, and was awarded a certificate of merit. He explained that the antirrhinums run six-foot stems, with about eighteen-inch spikes. They were grown very cool, with plenty of air and little feeding in the usual depth of benches. The clarkias, exhibited by Mr. Broadfield and receiving honorable mention, cut four-foot stems. They were grown cool in six-inch pots.

A. D. Taylor, landscape architect, gave a very interesting talk on the problems of

Salem, Ohio

the landscape gardener. His talk, which was enjoyed by all, brought a closer insight into the problems and difficulties of that branch of the gardening profession.

W. J. BRUCE, Sec'y.

THE NORTH SHORE, ILL., HORT. SOCIETY

The regular monthly meeting of the above society was held on April 10 at Anderson Hall, and was well attended. President J. R. Clark occupied the chair. There was a lively discussion of the chrysanthemum schedule for 1922. Chairman F. R. Kuehne, of the entertainment committee, made a final report of the recent smoker and a vote of thanks was extended to Mr. Kuehne for his efforts to make the entertainment a success. A splendid exhibit of cut flowers and pot plants was shown.

R. E. KUEHNE, Cor. Sec'y.

WESTCHESTER AND FAIRFIELD HORT. SOCIETY

The April meeting of the above society was held at the American Legion Hall, Port Chester, N. Y., on April 11. The Flower Show Committee reported progress and the monthly exhibits were fine. Awards were as follows: W. J. Sealey, first, for vase of roses; William Smith, second, for a vase of carnations, a good sport from the well-known Laddie; Alex Grieg, third, for vase of lupines. Other exhibits were H. F. Bulpitt, colored freesias; Alex Smith, lupines; John H. Troy, tub of hydrangeas.

John H. Troy, of New Rochelle, received a certificate of merit for Kourou Azalea.

Mr. Troy gave the members an interesting talk on the trees, flowers, and ferns which he saw on his recent visit to Australia and New Zealand. His talk was very much appreciated by the members and he was given a hearty rising vote of thanks.

HARRY JONES, Cor. Sec'y.

Now—A Power Mower for Medium Sized Lawns

For years Ideal Power Lawn Mowers have been used for taking care of large lawns. The thousands of Ideal Mowers in use have definitely demonstrated their labor saving, money making qualifications.

However, there are thousands of lawns hardly large enough to warrant the purchase of a large power mower, yet with so much grass to cut that proper care becomes a big problem—and an expensive problem.

It was for this vast number of medium sized lawns that the Ideal Junior Power Mower was designed. It is moderate in price, dependable, easy to handle, and costs little to operate.

The Ideal Junior is exactly the right machine for homes with lawns too large to conveniently care for with hand mowers—for mowing the putting greens on golf courses—and for parks and cemeteries as an auxiliary unit

for trimming up and cutting in close quarters.

For Larger Lawns the 30" Ideal Power Lawn Mower

For large estates, municipal parks, cemeteries, golf clubs, schools, colleges, etc., the well known 30" Ideal Power Lawn Mower has no equal. Does the work of 5 to 7 men with hand mowers. Costs about 50 cents a day to operate and soon pays for itself in labor saved.

Furnished with or without riding trailer.

For large parks, golf courses, etc., we build the Ideal Power Triplex Mower.

Write today and get our large pictorial catalog.

STATEMENT OF THE OWNERSHIP, MANAGEMENT, CIRCULATION, ETC., required by the Act of Congress of August 24, 1912, of "Gardeners' Chronicle of America," published monthly at New York, N. Y., for April 1, 1923.
State of New York } ss.
County of New York }

Before me, a notary public in and for the State and county aforesaid, personally appeared D. Ebel, who, having been duly sworn according to law, deposes and says that he is the business manager of the "Gardeners' Chronicle of America" and that the following is to the best of his knowledge and belief a true statement of the ownership, management (and, if a daily paper, the circulation), etc., of the aforesaid publication for the date shown in the above caption, required by the Act of August 24, 1912, embodied in section 443, Postal Laws and Regulations, printed on the reverse of this form, to wit:

1. That the names and addresses of the publisher, managing editor, and business manager are: Publisher, The Chronicle Press, Inc., 286 Fifth Ave., New York, N. Y. Editor, M. C. Ebel, 286 Fifth Ave., New York. Managing Editor, M. C. Ebel, 286 Fifth Ave., New York. Business Manager, D. Ebel, 286 Fifth Ave., New York.

2. That the owners are (give names and addresses of individual owners, or, if a corporation, give its name and the names and addresses of stockholders owning or holding 1 per cent. or more of the total amount of stock.)

The Chronicle Press, Inc., 286 Fifth Ave., New York, N. Y. M. C. Ebel, Summit, N. J. M. E. Burniston and J. A. Burniston, both of Summit, N. J. S. Warendorff, 325 Fifth Ave., N. Y. Chas. H. Totty, Madison, N. J. A. Bauer, Deal, N. J. I. Barnett, Sewickley, Pa.

3. That the known bondholders, mortgagees, and other security holders owning or holding 1 per cent. or more of total amount of bonds, mortgages, or other securities, are: (If there are none, so state.) There are no bondholders, mortgagees or other security holders.

4. That the two paragraphs next above, giving the names of the owners, stockholders, and security holders, if any, contain not only the owners,

Some First Hand Facts On Owning Your Own Greenhouse

We made our greenhouse catalogue with a determination to get away from the usual cut-and-dried treatments, and make it a **real help** to those who would know the genuine joys and advantages of greenhouse possession.

It tells interestingly of our every type of greenhouse and shows even more than it sells. It contains plenty of plans of practical layouts and is replete with vital information about greenhouses and conservatories. The text is told in a chatty kind of a way that makes pleasurable reading.

You are heartily welcome to a copy. The name is "Owning Your Own Greenhouse."

Continuous Interest in Gardening

The best gardens and the most mutually satisfactory all around relations are where owner, gardener and landscape architect can be continually improving the country place. With garden enthusiasts, the pleasure of discovering, planning, ordering and planting is as great as the pleasure realized from the results six months or six years later. The gardener knows that "if you love a plant, you can make it live anytime" is usually true. Owners as a rule do not know it. I asked Arthur Herrington at the Flower Show "Why do people think of planting in the spring only?" He answered, "Tradition."

Hicks Nurseries will help you out by planting and guaranteeing all summer. There are perennials in pots and things that can be dug up with a clump of earth which will decorate the flower garden immediately. There are some good varieties of perennials here and the colors can be selected in full bloom to carry out a color scheme. After the first week, the plants will take hold and give satisfaction this year, and next year be like an old garden.

Shrubs often need revising, and gardeners tell us the time to prune is just after flowering. Old shrubs can be safely moved in July and new better colored, or more up-to-date varieties added. We have many of the new and rare varieties introduced through the Arnold Arboretum and Highland Park, Rochester ready for planting all summer.

Shade trees were once considered movable with safety only in early spring or late fall. You can obtain from Hicks Nurseries hundreds and thousands of lindens, maples, oaks, beeches, tulip trees, hornbeams and cucumber magnolia six to thirty feet high in full leaf in June, July and August. Lifted and moved by our careful, common-sense system, trees keep right on growing better than if transplanted in the old way. A few may drop some of their leaves and look wilted and yellow for a month. They will recover.

Evergreens are delivered with a ball of earth. With our system of root pruning and transplanting they produce a lot of fibrous roots close to the ball. With coarse long-rooted species like Pinus Austrica and Abies Concolor the old method of waiting until August is no longer necessary. Such fibrous rooted evergreens as Thuja, Retinospora and Rhododendron, can be safely transplanted when the growth is soft in May and June.

Fruit trees, berry bushes, grape vines, rose bushes and vines are available in pots and tubs for immediate bearing.

Gardeners are in a position of authority to encourage summer planting. We will do our part and thank you for suggestions on how to do it better.

286 Fifth Ave.

New York

This association is in no sense a trade union organization, but includes in its sustaining membership owners of some of the foremost country estates in America.

SPRAYING

is as

Essential as Fertilizing

Successful cultivation demands a knowledge of the habits of plant insects and diseases, and the proper remedies for their control.

APHINE, an effective remedy against all sap sucking insects infesting flowers, fruits and vegetables, is free of the disagreeable odors and features of most insecticides. It invigorates plant life and is unexcelled as a wash for decorative plants. Aphine will not injure the most tender flower or foliage.

FUNGINE is an excellent remedy for mildew, rust, and other blights. It is readily soluble in water and contains no sediment. Fungine does not stain the foliage but cleanses it.

VERMINE is a soil sterilizer and vermicide. It destroys cut, wire, eel and grub worms, maggots, root lice and ants, and will protect your gardens and lawns from ravages under the soil.

There is but one convincing way for you to become familiar with the merits of these products and that is to try them out for yourself. It will prove worth while.

Sold by dealers in various sizes.

Make Your Garden Serve You All Summer

and also produce a sufficient supply for
winter use.

DREER'S MID-SUMMER CATALOGUE

contains a list of many things which may be planted
during the summer months. You will find listed all
that is best for late planting in Vegetables, Winter
and Spring Flowering Bulbs. Also the dependable
strains of Farm seeds for Summer and Fall Planting.

Pot-grown Strawberry Plants of the leading sorts and
Celery Plants of best varieties.

Also up-to-date Garden Tools, Insecticides, Fertilizers
and all the helps that make gardening a pleasure.

Write for a free copy and kindly mention this publi-
cation.

King GREENHOUSES

This simple, dignified King Greenhouse is
situated in a small public park. It illustrates
how every King is designed to both fit its
surroundings and suit the purpose for which
it is intended.

Catalogues, estimates and designs for greenhouses,
conservatories and glass enclosures for all uses.

A PRACTICAL HANDBOOK OF
TREES, SHRUBS, VINES and
HERBACEOUS PERENNIALS

By JOHN KIRKEGAARD

Formerly Assistant to Director of the Royal Botanical Gardens, Copenhagen, Denmark. Latterly Twenty Years in American Forestry and Botanical Work

Illustrations in Sepia. Planting Plans. 410 pages. 8vo. Beautifully bound in cloth. Price \$2.50 net. Mailing price \$2.71.

This practical reference book is the logical result of years of Practical work in the author's career. He has sought, and successfully, the simplest form of explanation and instruction in the message which he conveys from each plant and growing thing to the amateur or gardener who seeks to be tree-wise, shrub-wise and vine-wise. No book of recent years is so comprehensive and so practical as this volume. Exhaustive descriptions, variations from type and more technical matter must be sought in the Horticultural Encyclopedias, for in these pages the author stands as the interpreter of the plant to the planter. The character of information may be summed up in the sub-title of the book—THE HARDY AND ORNAMENTAL VARIETIES: THEIR CHARACTERISTICS: USES: and TREATMENT.

Adequate space is given to articles upon injurious insect pests, the adaptability of plants for certain purposes, planting, pruning, spraying and cultivation. In short, the author has endeavored to include whatever information the householder needs with which to secure the proper selection, care and treatment of such trees and plants as are best adapted for his purpose, then to aid him in properly caring for them.

Things and Thoughts of the Garden

MONTAGUE FREE

THE appearance of a fine show of bloom on *Clerodendron Thompsonae* (*C. Balfourii*) at this time (May) is a reminder of what a splendid greenhouse climber we have in this species. In spite of the fact that greenhouse climbers in general seem to have fallen upon evil days and are less in public favor than formerly, the Glory Vine, giving it its English appellation, is still fairly commonly grown. Those who are unfamiliar with it may perhaps obtain some idea of its beauty from the following description: It is a strong growing shrub, climbing by means of slightly twining stems, with rich dark green foliage which provides a pleasing foil for its flowers. These are produced in loose cymes from the tips of short lateral branches. The calyx which persists for a considerable time after the corolla has fallen, is creamy white in color, strongly five-angled and in general outline pear shaped. From its narrow end the brightly colored corolla emerges with its three upper petals reflexed. The protruding stamens and pistil serve to still further enhance the distinctive character of the inflorescence. The color of the corolla is described in Bailey's "Cyclopedia" as light crimson, which is probably accurate enough for all practical purposes. An attempt to match its color in Ridgway met with partial failure and the nearest approach found to it in that valuable book was "carmine." The true color appears to be between "carmine" and "spectrum red."

One satisfactory feature of this *Clerodendron* is its good temper under cultivation—it may be greatly neglected but it still continues to produce its crops of bloom from May onwards throughout the Summer, year after year. If abundant flowers are desired, it is good to allow it to become somewhat pot bound once the desired size is attained, as this tends to curb its rampant vegetative growth and promotes the formation of the short laterals on which the flowers are produced. It is not especially ornamental when trained along the greenhouse rafters as the inflorescences are erect and almost invisible to anyone standing below because of the dense mat of foliage. It is seen to best advantage when grown in a pot or tub and trained upon a wire frame or a supporting pillar. It is native to W. Africa, but thrives even if subjected to a minimum Winter temperature of 50 to 55 degrees, when it is more or less dormant.

Another indoor *Clerodendron* that is quite showy is *C. fallax*. This is a shrub that produces its terminal cymes of scarlet flowers throughout the Summer. Like the preceding it is noteworthy because of the lengthy

period that it remains in bloom. Although a shrubby plant it is perhaps best treated as an annual, as it appears to better advantage, with a larger inflorescence, when grown to a single stem. Old plants that have been cut back tend towards irregular branching and an ungainly shape. This species is indigenous to Java and does best in a warm house. Incidentally the genus has a fairly wide geographic distribution as representatives are found in Africa, Australia, East Indies, India and Japan.

There is at least one member of the genus that is comparatively hardy, namely, *C. trichotomum* from Japan. This is an extremely attractive shrub and valuable in its late blooming habit. It forms a bush with a rounded head and is conspicuous when covered with white flowers backed by the reddish brown calyces. It remains in bloom for a long time and, after the flowers have fallen, the bright, dark blue fruits seen against the persistent red calyces provide another attractive display. The fact that the leaves are held until well into the Fall is another recommendation for this little known shrub.

With regard to hardiness, here in the Brooklyn Botanic Garden it comes through most Winters unscathed. Last Winter, for example, the tips of the branches were killed back from three to six inches, which is only to be expected when growth is maintained until late into the Fall. In very severe Winters it may be killed back to the ground, but this does not necessarily mean the loss of a crop of flowers, as these are produced on growth of the current season.

* *

Mention of *Clerodendron Thompsonae* as a greenhouse climber calls to mind other plants, suitable for this purpose, some of which are all too seldom seen.

The Calico Flower, *Aristolochia elegans*, from Brazil, is extremely decorative and interesting, and is most valuable when a not too rampant climber is desired. Although its flowers are not so spectacular as those of *A. gigas*, for example, they are quite showy, and, as another redeeming feature are devoid of the intolerable stench that makes those of *A. gigas* and many others of the genus so objectionable in a closed greenhouse. It is a free bloomer and the flowers, pendent in slender pedicels are about three inches in diameter. The ground color is white, with curious purple markings, and a velvety blotch of rich purple at the throat.

Another interesting stove climber is the *Granadilla*—one of the Passion Flowers—*Passiflora quadrangularis*. The Cambridge (England) Botanic Garden is the only

establishment where we have seen it growing vigorously, and blossoming and fruiting freely. There it was planted out in the "stove" and its long strong shoots were trained along the roof. In the Summer when its fruits ripened there were many delectable feasts in the potting shed, at which the juicy pulp of the *Granadilla* was the *pièce de résistance*. These fruits are quite sizable, 5 to 6 inches long, greenish yellow when ripe and present an attractive appearance when hanging on the vine. The flowers, 3-5 inches across, are sweet smelling and amongst the most showy in the genus. The prominent part is the five-fold corona of white filaments variegated with violet, which is backed by the petals, white without and red within. This species comes from Nicaragua, and enjoys a warm Summer temperature.

The "Purple Wreath" *Petrea volubilis*, which grows wild from Cuba to Brazil, when seen at its best, is one of the most striking of our ornamental climbers. The flowers are produced in long racemes and the color scheme is one of lavender and violet. The five-lobed calyx is lavender in color and persists after the violet corolla, which is much smaller than the calyx, has fallen. The plant grows vigorously with us here but is rather shy so far as blooming is concerned. Possibly a little starvation, or perhaps Summer pruning when growth is rampant, will help matters in this respect.

* * *

The Scotch Broom, *Cytisus scoparius*, was very satisfactory with us here this year and a large bush smothered in yellow flowers tinged with orange was one of the prominent features in the rock garden. According to Gray's "Manual" it has become naturalized from Nova Scotia; S. E. Mass. to Virginia, and southward. It seems somewhat surprising that it should have become established so far North when its behavior in Brooklyn is considered, for here it is not infrequently killed by the Winter. To the best of our recollection last year was the first time in eight years that it bloomed at all adequately. It often happens that although the plants may not be entirely destroyed, their branches are killed to the ground, and, as the flowers are produced on wood of the preceding season, it proves a disappointment to those expecting a great May display.

Its lack of hardiness in some gardens may possibly be due to its being planted in soil that is too good for it. The Broom grows naturally on barren sandy soil and when introduced to the rich soil of gardens is inclined to make sappy growth quite unsuited to withstand our rigorous Winter climate. Another possible explanation is that the plants that so readily winter-kill originated from stock obtained from the warmer parts of its range. It seems reasonable to suppose that plants raised from seeds obtained from, for example, a station in the mountains of Scotland, would have a better chance to succeed in our climate than those obtained from Southern France.

Apparently at one time the Broom was of considerable economic importance being used in medicine; as forage (mainly for sheep); as a condiment, the flower buds being pickled and used in the same way as capers; for thatching, for making brooms and divers other purposes.

There are several garden forms of *Cytisus scoparius*, which are reputed to be less hardy than the species. One of the best of these is *C. scoparius* var. *Andreamus* which has flowers of yellow and crimson.

* * *

The *Laburnum*, too, this year delighted us with a display of its long, yellow racemes. This of course is a sort of cousin to the Broom and in Europe is sometimes used as a stock on which to graft varieties of *Cytisus scoparius* when standards are desired.

One would do well to hesitate before using flower buds of the *Laburnum* as a substitute for capers, as is done with the Broom, for it is quite poisonous and, in England, the demise of the children from eating the seeds is occasionally reported in the newspapers. Apart from this bad trait it is a glorious tree for garden purposes in sections where it thrives. We remember a fine specimen in the garden of Childerley Hall in Cambridgeshire, England, that appeared as though it might be a grandmother (or grandfather) of all *Laburnums* so gnarled and ancient did it appear. Although so aged, it had not lost its powers of blossoming as a photograph taken a year or two ago showing it laden with bloom, testified.

In our climate the young branches are sometimes Winter killed, and, as it is from these that the flowers are produced, an annual crop of bloom cannot always be relied upon.

Laburnum alpinum is reputed to be the hardiest of the genus and our gardens would be greatly enriched if someone would take this species in hand and develop a strain capable of withstanding our Winters unscathed. There is ample room for a tree with yellow flowers, blooming in May.

* * *

Here is another quotation from W. H. Hudson's "A Shepherd's Life."

"But let us look at the true cottages. There are, I imagine, few places in England where the humble homes of the people have so great a charm. Undoubtedly they are darker inside, and not so convenient to live in as the modern box-shaped, red-brick, slate-roofed cottages which have spread a wave of ugliness over the country—but they do not offend—they please the eye. They are smaller than the modern-built habitations. They are weathered and colored by sun and wind and rain and many lowly vegetable forms to a harmony with Nature. They appear related to the trees amid which they stand, to the river and meadows, to the sloping downs at the side, and to the sky and clouds over all. And, most delightful feature, they stand among, and are wrapped in, flowers as in a garment—rose and vine and creeper and clematis. They are mostly thatched, but some have tiled roofs, their deep, dark red clouded and stained with lichen and moss; and these roofs, too, have their flowers in Summer."

"But its garden flowers, clustering and nestling round it, amid which its feet are set—they are to me the best of all flowers. These are the flowers we know and remember forever. The old, homely, cottage-garden blooms, so old that they have entered the soul. The big house garden, or gardener's garden, with everything growing in it, I hate; but these I love—fragrant gillyflower and pink and clove-smelling carnation; wallflower, abundant periwinkle, sweet-william, larkspur, love-in-a-mist, and love-lies-bleeding, old-woman's-nightcap, and kiss-me-John-at-the-garden-gate, sometimes called pansy. And best of all and in greatest profusion, that flower of flowers, the marigold."

Gardeners can appreciate the beauty of Hudson's description of the humble English cottages and their gardens, and enthusiastically sympathize with his love for the old cottage-garden blooms, but most of us will simply fail to understand how he can hate the "gardener's garden" with everything growing in it. The objection of a Nature lover to the prim formality to be found in some gardens, his scorn for some of the highly developed monstrosities that are cataloged as "improved" varieties can be understood, but not such wholesale condemnation of everything that grows in the gardener's garden.

Fall Bulbs

GEORGE H. PENSON

NOW that the Spring rush is over and the majority of planting done, the exception possibly being some successions of vegetables, our thoughts are ahead, as ever they must be, to the requirements of next Fall, Winter and the Spring of 1923. One of the main things to be thought of on many places are bulbs for Fall planting and also for forcing in the green house during the early Spring months, which will herald once again the approach of another Spring. The many varied forms and colors of forced bulbs are ever suggestive of youth and Springtime even though the weather on the outside may be part of a dreary Winter or a boisterous windy or stormy day of March. The Paper White *Narcissi* and Roman Hyacinths will be the first to show us Spring flowers, even though Christmas is only days past. These will be followed by narcissi of many varieties, hyacinths, tulips, crocuses, and later, probably one of the last, irises,

but do not forget a poor bulb cannot produce a good flower no matter what the soil and conditions are. Where the beds have been planted all Summer to other flowering subjects it is advisable to spade under well rotted farm yard manure when preparing for bulbs. This should be decayed so that it will easily pulverize and readily mix with the soil. With plenty of available plant food we often see good flowers produced on lighter soils, but, as nearly all bulbs like an abundance of moisture a heavier soil is more conducive to this end.

Planting.—When planting fruit trees and other like subjects we study the depth of the roots in relation to the air and food to be applied at the needed season. This does not enter into the growing of bulbs to any great extent but the depth of planting is just as important. Another thing to be borne in mind is that the bulbs we plant in the Fall have to go through the Winter and while freezing

at a good depth will not hurt them it would not be advisable to have them near the surface. I like to see from four to six inches of soil on the top of the bulbs when the bed is finished off. Darwin tulips particularly want to be planted deep. Crocuses will be an exception to this rule, one inch being sufficiently deep enough for them, especially if the soil is heavy. They have a tendency to rot if planted deep. When planting, the most satisfactory way that I know of is to make up a rough sketch of the beds at the time of ordering the bulbs; lay out on this exactly where each variety is intended to be placed and be governed by this at planting time. When the beds are ready to receive the bulbs mark them off and place each bulb exactly where it is to be planted as they are removed from the bag or box. Lay your whole bed or beds out in this way before any are planted and this will eliminate much confusion. When so placed do not attempt to change or alter them

A display during May of Darwin, Breeder, and Cottage Tulips on the estate of J. E. Aldred, Ormston, Glen Cove, L. I. (Courtesy of Stumpp & Walter Co.)

both Spanish and Dutch. Not only do we have to think of greenhouse requirements but on an ever increasing number of estates do we find an extensive planting of bulbs made for a gorgeous display of color from earliest Spring when the snowdrop and crocus will herald the way for others of nobler birth, with a continuation of flowery wealth until the last tulip has dropped its petals when the month of May is on the wane. These plantings may be an entire formal garden having a Dutch effect when the bulbs are in bloom or massed in the herbaceous border, the wild garden, or edging for shrubbery. The later flowering tulips are not very adaptable for the latter, the other subjects can be planted to better advantage, according to the season it is desired to have them in flower.

THE SOIL

A medium heavy soil with plenty of depth having an abundance of available plant food produces the best re-

sults, but do not forget a poor bulb cannot produce a good flower no matter what the soil and conditions are. I like to press them into the hole made with an ordinary garden trowel. When planting Spanish or Dutch iris it will be beneficial to drop an inch of sand in the bottom of the hole placing the bulb on this and covering with soil.

Where we find a Dutch garden laid out in a number of small beds forming a formal design it will often be the most effective to use one color to a bed, the exception perhaps being an outside edging. A nobler effect will be secured by having a larger block of one color than trying to get too many in a small space. And while speaking of color we have the proverbial "all colors of the rainbow" when we think of tulips and hyacinths, but narcissi are more limited. The latter are not extensively used for formal bedding. They have a more natural effect when planted in the wild garden, edging of shrubbery, or even

a portion of the lawn not seen from the mansion, a vista flanked with narcissi makes a very pretty sight. Take the old *Poeticus ornatus*, or any of the larger flowering varieties and they will add beauty during the early Spring months. The narcissi and crocuses seem to be in their natural home in these places but not so with the hyacinths. The tulips and irises are in a utility class. Should it be intended to leave bulbs so planted more than one season care must be taken to insure a finishing of the bulbs by letting them make their natural growth of foliage. This must not be removed by cutting until it shows signs of relaxing and decay, typifying a finished growth. The longer this remains intact with the bulb the better the flower will be the next season. In fact if it can be left to decay away on the bulb it is beneficial to it. When planting in formal beds, particularly tulips, due consideration must be given to the height at flowering time. All varieties listed will show the height and if followed will be of great assistance in getting the required effect. This is not so particular with other things as with the tulips, but a thirty-five inch Darwin will certainly look out of place on the edge of a herbaceous border. Placed further in the rear they will have a very pleasing effect.

THE SEASON

Snowdrops are the first of the bulbs to make their appearance and also their flowers. When a boy, I searched for the tiny tips of the snowdrop's growth amongst the melting snow in sheltered places on the edge of many evergreens. This to me was the first sign of Spring. Following the snowdrops come the crocuses with their many brilliant colors. Following these we have early flowering tulips and hyacinths, narcissi and late flowering tulips which will cover a flowering period to the end of May.

Varieties and colors.—When we look through any bulb catalog and note the different classes of tulips, early flowering, both single and double, Darwins, Cottage, Dutch Breeders with the maze of color they represent we have quite a study before us to make a selection of such varieties which are best adapted to our particular purpose. The color scheme and season of flowering will have to be the chief factors in determining what varieties to order. Hyacinths give us an abundance of color but the season is not so extended nor do we have so many classes to select from. The Roman hyacinths are not adapted to outside culture. Narcissi give us a wider range of type but not so much in color as the tulips. We have the hardy *Narcissus poeticus* in several varieties and *Narcissus poeticus* likewise in four or five varieties. These are a very distinct class as the petals are white forming the major portion of the flower, the trumpet being negligible. The jonquils are the smallest of the trumpet varieties and are only used for mass planting in the wild garden or shrubbery. The most magnificent things to be found among narcissi are the giant trumpets: Empress, Emperor, Golden Spur, and the newer King Alfred is always gorgeous. Then we have the medium trumpet class, signifying as it does that the trumpet portion of the flower is smaller than the giants. This is oftentimes made up by a variation in color of the perianth. These are now classed under three groups, viz.: *Barrii*, *Leedsii* and *Incomparabilis*, which denotes the length of crown or trumpet and color of petals. Double narcissi can be had in such varieties as Von Sion and *Albo pleno*, the latter being nicely scented. Dutch or Spanish Irises are best used for cutting purposes, planted in such positions as will allow them to be cut when needed. These compete with the *Schizanthus* for the "Poor Man's Orchid" and I think they are entitled to win out as they more closely resemble the orchid in shape

and have as much color. We often see the colors running together in an individual flower very similar to many Cattleyas. They are listed in separate colors, the predominating color, but if a mixed color is wanted for a vase or cut flowers these irises will supply it.

BULBS FOR FORCING.

All bulbs will respond to forcing. Some can only be brought into flower a few weeks ahead of the normal flowering season, but others will respond to heat and moisture and flower at any desired season. Some varieties respond much more easily than others and should be used for the earliest flowers. Paper White lead the narcissi, Roman hyacinths lead the hyacinths. Among tulips use the early singles. The old Mon Tresor will be found to stand as much pushing as any of them. Get the bulbs intended for early forcing potted up as soon as possible, using a good rich, fairly heavy soil, if same is easily obtainable or any good sweet soil. While it is not possible to put them as deep in the pot, pan or flat as can be done in the open ground they should have the bulb covered with soil. When potted plunge the pot, pan or flat, whichever is used, into six or eight inches of sand or sifted coal ashes. I believe it is better to plunge the earliest patches deeper than this as they will not feel the heat so much. The plunging or complete covering of the bulbs is to retard top growth and promote root action by keeping them cool and moist. Here is the secret of forcing bulbs: Get the root first and the top will come without any difficulty. If you try to force any kind of bulb only half-rooted the result will be very disappointing. When rooted they can be taken out of the sand and if they are not all needed some can be held in a cool house for several weeks. There is a limit to the time that they can be left in the sand, as they will try to push up when the roots reach a certain stage. They ought to be examined periodically and taken out as soon as any top growth is noted. At no time does it pay to give bulbs a great heat as they are all cool subjects. At night 55 degrees will give the best flowers. Where quality has to be sacrificed for earliness this can be increased. Romans and Paper Whites will stand more heat for a time but should be allowed time to harden up in a cooler house to stiffen the stems before they are cut. Hyacinths if subjected to excessive heat will have a very weak stem and fall over without the support of a stake. Darwin tulips and irises should be the last to be brought into flower, preceding those grown outside by a few weeks. During the whole growing season all bulbs like an abundance of water. Many are grown in special glass jars or vases by amateurs in water alone. Others are grown in bowls filled with pebbles and water, the roots working in among them. The large flowering hyacinths and narcissi are best adapted to this work. For those growing in the soil, liquid manure applied when the flowers are raising will help them along, but it is not advisable to use fertilizer of any kind. Liquid cow or sheep manure is best adapted to them. Keep a moist atmosphere around them and a good bulb will produce the best in flowers. When any one wishes to get the maximum in flowers from any bulbs the best bulbs that can be bought will be none too good. Order early which will be appreciated by the seedman and you will not be disappointed yourself.

Nothing is easier than fault-finding. No talent, no self-denial, no brains, no character, is required to set up in the grumbling business. But those who are moved by a genuine desire to do good have little time for murmuring or complaint. ROBERT WEST.

What is a Garden? Some Random Thoughts

HENRY J. ECKSTEIN

THE various books on gardening of the last decade largely concern themselves with the revolutionary trend that has so completely reversed the landscape and gardening practice of this century. From the regularity and severe rigidity that typified the entire spirit of the Victorian era, to the semi-wildness, towards which the tendency of our time so often leans, is indeed a long step. Naturally there is much controversy as to the extent that a garden shall be formal or naturalistic. What shall determine the extent to which these contrasting elements shall enter into the planning of the garden? It would seem that this would be a matter to be determined only by the individual who is trying to make a garden as an expression of himself. But before these questions are at all to be considered might it not be well to attempt to say, what, after all, is a garden?

This, too, it might be said, must of necessity be determined by each one, individually and for himself, and in expressing an opinion as to what a garden is, this is not only conceded but accepted as a premise to the answer suggested. For if we say that the garden must be the expression of the person making it are we not obviously concluding that only when a personal note enters into the garden form is there a garden at all?

Whosoever loves flowers and devotes care and time to their cultivation, placing them and growing them, in such places and ways as are at his disposal, creates thereby a garden. It matters not where the garden is, or what is its nature or form, or size. Can we feel, if we consider the spirit and not the technique of the matter, that we can use the magical word, garden, with all that it implies, of loveliness and fragrance and sentiment, unless it conveys something of the interest that causes it to be at all?

We have all passed by a simple cottage or isolated farmhouse and seen beside it a few scattered plants irregularly placed, perhaps even self-perpetuated, and felt the hand of the gardener, despite their straggly and unrelated appearance. We know that the farmer who is trying to make a living out of the land has no time for any such luxury as flowers. Usually it is the farmer's wife who attends to the few plants there are and makes for them the home they have even though she as well has but little time for them. Often their location is unsuited and their number few, their whole appearance inharmonious, but despite this, in fact often even just because of it, we somehow are impressed with the feeling that someone is making a garden.

Even in our large cities, in the most congested and barren districts, we see an occasional window-sill with one or two pitiful looking plants, or a rudely made box, in which someone is struggling to coax a little growth, in face of every adverse condition. Who will refuse to grant that these also are gardens, not because of their beauty, for often they lack it completely, but because of the love that lies behind their existence?

We also see in large cities on palatial homes or luxurious hotels sumptuously planted window boxes that show every care of the florist and much expenditure. At least to me there is no feeling of a garden there and no thought of the spirit however much they may ornament or decorate the building.

So that in every circumstance, wherever flowers are planted with feeling and cared for to the utmost extent that the surrounding conditions permit, we have the spirit, at least, of the garden. And wherever the personal note of the grower is missing, and the result, however,

elaborate and effective, is but the outcome of an order given to have so and so done, there is no true garden. From the humblest city window to the largest country estate this seems equally true.

Some years ago I visited one Summer day two gardens of note in an American resort, famed possibly above all others for the extent and glory of its gardens. One belonged to rather a simple, unpretentious place, particularly for its environment. But immediately there came that feeling of the individual direction that made its garden successful. In fact there was a series of gardens, each perfect in itself and leading one to the other in so skillful a way that one was never aware that another lay just the other side of the encircling shrubbery.

The other was a great estate with elaborate floral displays, arranged in regular, disconnected beds. Its chief gardener was proud of his display in two huge, round beds of contrasting red salvias and yellow coxcombs, which fortunately for me, were not yet in bloom. He enjoyed the opportunity of conducting us through the great greenhouses and of telling how many roses he cut and shipped each Winter. I think it was some twenty thousand. He rejoiced in describing the rarity of his orchids and the extraordinary size of his "mums." He told of his appreciation of the opportunity of showing all this, because his employer was rarely there, and even then never visited the "gardens."

I will admit that this owner and his superintendent have every technical right to the use of the word "garden," but will always feel that to any true garden-lover they maintained a great and elaborate flower factory, that efficiency supplied the large demand for cut flowers made upon it, but in no sense and at no time can we feel that all this elaboration and work made a garden.

Of course, on the other hand, we cannot urge that merely the love of flowers makes a garden and these are extreme cases cited to convey the underlying thought that the true garden spirit is felt wherever the effort is made to cultivate flowers because they are fully appreciated. But one also demands that all possible efforts and provisions are made to ensure the success of the plant and its most advantageous display. There are many who prepare regularly laid out beds or straight, perfect rows, growing in them and carefully cultivating giant cannas, perfect dahlias or even rarer flowers. These people may indeed truly cherish these; in fact they usually do, but they have failed to provide for their best effect, in their lack of taste and harmony.

A garden requires the judicious use of material and background, the employment of a sense of fitness and beauty and the true appreciation of the full value and habit of the particular specimens selected. All this should always be taken into consideration not only by the maker of the garden but by its critic as well.

Formal shrubberies, well clipped hedges and even walks or beds of flowers cannot look well in a rural or semi-wild district, surrounded by rough fields and embracing woodland. No more is a wild naturalistic effect in keeping with the suburban cottage that fronts a paved sidewalk and is flanked almost contiguously with neighboring houses. These are facts admitted by all writers on the subject. But just how far formal design can enter into an isolated country place or naturalistic tendencies can be admitted in the suburbs is always a question which the creator must determine. The secret of success or failure lies in the taste and discretion that determines the

introduction of whichever of these elements is foreign to the environment. Where design or its absence is consciously blended with surrounding conditions, and all skillfully harmonized, a garden arises.

Wherever love is there is a garden, but it must be the love that cares and provides and considers all contributing aspects. No one can build a garden in a single year. In fact age gives a tone to a garden that can not be produced by man.

And here the individuality of the gardener having expressed itself meets the competition of the individuality of the garden. Conditions of soil, drainage, situation, climate and surrounding vegetation all seriously affect the plans of the gardener and make themselves felt adversely or favorably.

When we start to plan our garden we are flushed with dreams and ideals. I was about to say "hectic," and I do not know but that is closer to the truth. We are led on and tempted by the catalogs for which nothing is difficult but all is beautiful and luxuriant. For the writers of these there is no drought and no wet spell. They never saw an aphid, or any other pest, and as to failure to bloom, well, that only happens with the stock of other nurserymen. So that our eager visions are enflamed by what we read in the catalogs. And we start to build. We conceive a picture of lovely lawns and shading trees amidst which we can sit and enjoy the lovely bloom of our new garden. We plan great masses of sumptuous, tall growing flowers, against relieving backgrounds of the fresh green of shrubbery, and fringed with delicate edgings, graceful and colorful. But when we have planned and planted we learn that the shrubs rob the soil, at the expense of the flowering plants, their roots trespass and encroach, and the larger plants crowd out and overshadow the smaller. Our plans are rent asunder, and—we start afresh.

Again we plant a variety of things, carefully chosen from the long lists, ensuing a succession of bloom, subtle contrasts of color and size, and then we find that conditions that suit some, do not suit others, our bloom is neither continuous nor well blended and we must plan again.

The garden, too, has its say, and until we have studied and reworked our schemes, until we have conquered, in one way or another, these obstacles we are not content. But the true gardener goes on, year after year, full of hope and joyful expectancy in the Spring, followed by new and greater plans in the Autumn. And between these seasons comes a period, usually about mid-Summer, of despair and trial that too often ends the effort. This period comes to all, but the real gardener survives and persists. And of course he never finishes. Nature and time, however, outlast the best gardeners, and when left alone often produce a lovely garden, perhaps not perfect in its completeness, but with an added charm of abandon and luxuriance that we can never hope to imitate. We often hear and read of the charm of old gardens, but that charm we can never produce, except if favored with a long life at garden making. But we can make the start, feeling that if we can never see the end ourselves, some one else may.

I have seen many such old gardens, neglected for decades, where no new plants have been planted for years, no weeds ever pulled, no order established. Often they have been almost entirely without bloom, at times gay with color. But always there has clung to them a quaint and desolate beauty.

In the old French quarter of New Orleans there are many such. We peer through dilapidated gateways or over half demolished walls. Behind them we see, in the courtyards, numerous children and burdened wash lines

that tell the tale of the gradual change from stately mansions to overcrowded tenements. Here is an old pavement, discarded well, abandoned garden, rank with growth, entangled with vines, and gay blossoms everywhere. The very desolation is its loveliness, the abandonment its charm.

In Charleston (S. C.) there are many such gardens, where the roses have outgrown our fondest dreams, in size and bloom, where the vines are massed with yellow or purple *Bignonia*. *Wistaria* never seems to bloom so well as in these forsaken corners. Ivy has encroached over all making a full, dull background for the brighter colors.

In Virginia, the ivy creeps from tree to tree, over the roofs of the houses, runs along the ground entwining great shrubs and flowers. Perennials seem to thrive the better, and the annuals almost seed themselves on its leaves. Amidst this overgrowth rambling walks are just traceable, by the lovely discoloration of their stone or brick.

Often these seem to be the loveliest of all gardens, even where they are just a wild tangle. The care and thought that laid them flourishes still, wafting the spirit of the forgotten builders with the fragrance.

I revisited recently a very old house in New England, a charming as well as historic landmark. I recalled the old garden that was an irregular, overgrown mass of entangling plants, and asked to see it. The new occupant proudly conducted me to a newly made garden. It was charmingly built, with lovely walks of brick, among well selected and grouped flowers and shrubs. Any other place I would have been delighted to find so excellent a garden. But despite its beauty, and choicer, greater bloom, I could not but regret the charm of the old one, that had been sacrificed to it.

It is in these old gardens that we learn to know that the garden too has its personality, that left to itself, it allows some things to grow and spread about, where others die out, and time adds its color, not of efflorescence, but of something equally beautiful, and of a more delicate sentiment. We cannot, as I have said, imitate this effect, it is a privilege Nature keeps for herself, but we can allow it some scope in our gardens, and often learn thereby.

Occasionally a plant will seed itself and thrive better than where carefully tended in greenhouse, frames, or nursery. And these self-seeded plants, arising unexpectedly amidst almost anything, or in some forgotten corner, are always a delightful surprise. Never have any foxgloves I have planted seemed so precious and lovely as some I found that had "volunteered" on the edge of the woodland.

Hollyhocks to me have always demanded a particular situation. They belong to small cottages, against its walls or fence palings. They always have seemed out of place in most formal and larger gardens. I have tried them in various places, and never been pleased with the result. Or when I have planted them in a place I thought exactly suitable, they have never grown. Still this Summer a few seedlings established themselves, fully one hundred yards from any place I had ever put them. They chose the very corner end of the border, against the vine clad arbor, with its heavy profusion of Dorothy Perkins. There they rose, six, eight, ten feet, from the midst of some phlox, alongside some *Thermopsis* that had finished blooming, and gracefully, although uninvited took their place. To me they were the loveliest bits in the garden this year, especially as they chose to come in lovely delicate shades of pink, white and yellow—and of course single varieties. Landscape architects

Rhododendrons and Azaleas in the Garden

FRANK B. MEYER

(Continued from May issue)

ARRANGEMENT IN THE LANDSCAPE

AT Lindenhurst conditions such as Mr. Wilson describes for the ideal have been given nearly perfect form. Running down the glens of gentle slope are paths bordered by rhododendrons and azaleas that are all along backed by dogwoods, red and crimson oaks, pines, hemlocks and cedars. At certain points taller-growing native azaleas help to shield the hybrid rhododendrons, which, all obtained directly from England from seven to twelve years ago, include several varieties not found hardy at Boston. These plants, all under eighteen inches in height, were spaced suitably for their size. As they have grown there has been thinning out from year to year. The plants removed have been used to border other aisles and to flank new vistas opened up. These vistas, all successful, as must be admitted by all whose good fortune it has been to inspect them, are delightful at all seasons of the year; but they are most charming when the rich coloration of the azaleas and rhododendrons, with here and there a cloud of white involucre of the dogwood and large flecks of the pink, are seen against the foil of verdure held up by the lusty pines and oaks. And even before Nature lifts the curtain to reveal this lovely maze of color in such masses some of the sloping paths invite one with their edges brightened by stately Cottage, Darwin and Breeder tulips whose rich shades are given increased luster by their standing against the dark gloss of the broad-leaved evergreen shrubs.

Spots of relief in the midst of the banks and masses of the rhododendrons have been formed by placing into natural pockets or nests Catesby's *Leucothoe*, whose graceful racemes, so fragrant, are followed by a rich bronzing of leaf in the Autumn. The mountain laurel also, admittedly the most valuable broad-leaved evergreen native of America, and *Andromeda* or *Pieris floribunda* are employed, perhaps not quite so much as they deserve. The *Andromeda* presents the one objection of looking bad when going out of flower.

During the Summer the masses of green are enlivened by the blossoms of lilies, many of them native, dotted among the rhododendrons wherever there is even the tiniest clearing through which they may lift their belts.

In the large rock garden can be seen how well suited to such surroundings are some of the dwarf rhododendrons and many of the azaleas. These all appear well at the water's edge also, the brilliant *Hinodegiri* as well as any, in groups or in clumps. They make lovely pictures in combination with plants like the bamboo and the tamarisks.

THE METHOD OF MANAGEMENT

The method by which all this has been achieved is worthy of emulation. Since the rhododendrons were bought at the small initial cost none have been purchased for the enlargement of the plantings. They have now increased to a value of over \$100,000, many times the original cost. The dogwoods, more than one thousand in number, were obtained for little more than the cost of hauling them. Today Lindenhurst has acres of the finest naturalistic growth as the result of proper planting, handling and judicious thinning. At no other place in the country, perhaps, can there be found so successful a development.

But there are other magnificent collections of rhododendrons and azaleas. At the Widener estate, not far away, the broad-leaved evergreens are used to help out, in splendid style, the massive formal design. Here are some of the best specimens of *Rhododendron ponticum* in the country. At the Neubold estate, also, not far away from Lindenhurst, excellent plants of *R. maximum* can be seen. The largest plants, however, are probably those in Clifford Park, off Wissahickon Drive, recently made a part of the Philadelphia Park system. Here are specimens of the *Kalmia* also fifteen feet tall, very shapely and profuse in bloom.

An attempt to use among rhododendrons ground cover plants may be inadvisable in situations at all exposed and needing pretty heavy mulching. It may be interjected that in general it is not good practice to attempt to use around roses or other plants requiring careful cultivation any ground cover or filler that, in addition to hampering cultivation, may conduce to the breeding of insects or fungous growths.

The flowering is made much more profuse by picking off, in the Summer, all old blossoms and seed pods.

THE WINTER PROTECTION

Concerning the protection of rhododendrons in Winter nearly enough has been said or implied already. A point to be emphasized it that, as with all evergreen plants, the functioning of the roots must continue, at least to a considerable degree, during the Winter. In the case of rhododendrons, because their roots remain so near the surface, it is necessary to keep the ground from becoming dry for a period long enough to exhaust the life juices. Shading helps of course to retard transpiration and evaporation. Another object of shading is to prevent the rays of the sun from penetrating beneath the coating of moisture under which the "converted" heat will become imprisoned, or from burning the surface of the leaf by shining through the globules of water or ice that act as burning glasses. In the case of deciduous azaleas protection against the sun is, of course, unnecessary. On Long Island, upon the magnificent estate of W. R. Coe, the writer has been greatly pleased to find this Spring that *R. schlippenbachii*, with its exquisitely beautiful flesh-pink blooms, and several of the *Kurume* azaleas have wintered out-of-doors perfectly with very simple protection. Leaves and long grass were merely piled around the shrubs high enough to cover them. In this way it has been found feasible to protect sufficiently even such treasures as two plants of *R. schlippenbachii* nearly three feet tall; and they were most delightful to look upon. Herein is encouragement great indeed and the promise of beauty in gardens quite ravishing.

DISEASES

The diseases of the rhododendron are not many nor are they hard to combat. "On the leaves and even sometimes on the small branches, can often be seen swellings on which a kind of gall forms. These galls are caused by a fungus, called *Exobasidium Rhododendri*, which lives in the attacked part of the plant and causes it to swell considerably. After the gall has formed a small layer of white, waxy mold covers it which can be rubbed off easily. In this waxy substance the spores of the fungus are found, and when these come in contact with rhododendron leaves or branches a new area of infection is produced.

"The only way to overcome this pest successfully is to pick off these galls and burn them. It is possible that other leaves and branches may have been affected by the disease; but it is impossible to be sure till later. So it is advisable to inspect your plants occasionally to see if the disease is reappearing. On azaleas a similar fungus can sometimes be found which also forms galls. This disease is destroyed in the same way as that on rhododendrons."

A new pest, the lace-wing fly, must now be contended with. It has been brought upon plants of *R. maximum* from some of the southern states. Into the vicinity of Philadelphia it seems to have been introduced by plants obtained from England soon after the outbreak of the great war at a time when the British growers were obliged to omit the usual precautions. It is an insect scarcely more than the sixteenth of an inch long, not larger than a midge. There should be spraying, in May, June and September, with five pounds of whale-oil soap, half a pint of nicotine and fifty gallons of water.

Azaleas sometimes have leafspot—*septoria azaleae*, cured by spraying with lime-sulphur or paris green. Small crowded orange spore dots on the under side of the leaves do not much affect the plant's health.

PROPAGATION

Concerning the raising of kalmias, rhododendrons and azaleas from seed there appeared, nine years ago, an article from the pen of William Anderson, superintendent of the Bayard Thayer estate at South Lancaster, Mass., the gist of which it would be worth while to give here. He has raised several hundred thousand without difficulty. The seed should be gathered in November and sown in February or March in a house, in four parts of the leaf-soil, two of chopped sphagnum moss, and one of sand, all put through a fine sieve. Clean six or eight-inch pans should be filled one-third full of crock or rough material of other kind and tamped with moderate firmness. Sow the seed rather thickly and do not cover. Set upon a well shaded bench in a temperature of 55-60 degrees. In most houses little or no watering will be needed, after the preliminary drenching, for three or four weeks. Then, whenever the pans become fairly dry, water thoroughly with a very fine rose. Do not permit water to stand or to be excessive at any time. Pure moss can be used; but the seedlings then can not be transplanted so early nor so safely nor so easily. When three or four leaves have formed, in about three months from the time of sowing, transplant into small flats, with drainage, of soil made from eight parts of leaf-soil, three of loam and two of sand, and firmed moderately. For kalmias avoid the black peat, which is fairly good for rhododendrons and azaleas. The first Summer keep the flats in the greenhouse, for careful watering, and shade with frames of lath. If any indication of dampening off appears increase the ventilation and sprinkle the affected parts with hot sand.

If a cold frame is used sow around May 15 and let grow on in seedpans the first season, protected from severe frost the first Winter. They would be kept best in a cold cellar. The following May transplant into flats, using small tweezers with which to take hold of them. Place them into frames under glass, with a screen of lath above them, but with plenty of light and air admitted during the day. Remove the shades toward evening, but keep on the glass to protect against heavy showers. In April, or before the young plants make growth for the third season, transplant into frames, with soil only slightly firmed. Use light loam, into which fork three inches of leafsoil. Set the plants four inches apart and shade with lath till September 1, when remove the shade and expose to the full sunshine during the Fall months in

order to ripen the wood. At the end of October mulch with thick leafy covering and later cover with evergreen boughs also. Rhododendrons and azaleas grow more quickly than kalmias and need less care.

At Lindenhurst Mr. Dodds has found that the seed of various rhododendrons, both native and some of the hybrids, germinates very freely when sown in chopped sphagnum moss or in moss or leafsoil, in pans, in January. He will prick the plants off into boxes filled with two-thirds peat and one-third fibery loam. When large enough they will be planted out into frames and kept thinned out as they grow. In two years, it is expected, they will be large enough for the nursery row.

Of the azalea, both the native and the foreign, Mr. Dodds has had excellent success with cuttings. In 1920 he put the cuttings in in September in sand in the house. They took nearly four months to root. Last year he put them in in August and they rooted in four weeks, ninety-five per cent of them. Mr. Koster thinks that June cuttings are still better. Cuttings of the growing wood of rhododendrons are sometimes employed; but the percentage of those that strike, in the case of the tall-growing, both of the species and of the hybrids is small. The cutting should be of half-ripe wood, preferably cut to a heel, about three inches long, inserted in peat and sand, perhaps better under a bell glass, in August, and kept at a temperature of 45-60 degrees, increasing later to 69 degrees.

The best way to propagate rhododendrons, however, is by means of layers. The layers should be put down in Spring, preferably in March or April, according to one authority, or in early Autumn. Peat with a quantity of sand added is the best soil for the purpose. If the branch can not readily be brought down to the ground a notch may be cut half way through the branch so that it will bend but not break wholly away. Last season's growths make the best layers. Strip off a few of the lower leaves, then make a cut about one and a half inches in length with a sharp knife up the center of the shoot. This is technically called tonguing the shoot. Bend the prepared shoot very gently and fix it into the soil with some wooden or wire pegs in such a manner that the tongue formed by the cut points downward. See that it rests upon the soil at the bottom of the opening made to receive it and then press the soil firmly around the layer.

It is advised by some that the starting of the root growth can be advanced by merely twisting the branch a little, instead of tonguing the shoot, or by removing a bit of the bark.

Grafting upon seedlings should be performed in July, after the potting has been done in the preceding Spring. The plants are either kept growing in the house or carried through the Winter in cold frames. But to handle them in frames one needs two sashes, the one several inches below the other, and extreme care must be taken to protect against the sun. For the first week or so the plants are not disturbed in any way. They are left lying on their sides, partly covered with moss. After this first week and daily for the next three weeks the water clinging to the under surface of the lower glass must be allowed to run off by a slight tipping up of the sash. At the end of another week, during which the plants have been aired a little every day, some of the wild stock may be cut away. After the scion is well grown into the stock the wild stem is cut off completely. The lower sash is now removed and the plants stood upright. They can be put out in the nursery in the Spring at the same time as those that have been growing in the house. Instead of the *ponticum* should be used seedlings of the *Maximum* or *catawbiense*, for hardiness and permanency.

The Cultivation of Bromeliaceæ

DR. E. BADE

BY far the greater part of the *Bromeliaceæ*, found in the warmer parts of America where the air is saturated with moisture, are epiphytes. They do not take their food from the soil like other plants but indirectly from the tree upon which they live. Nourishing salts, etc., are washed down to the plant from the tree upon which they have built their home. The green stalkless leaves which form tightly joined rosettes with spoon shaped elongations collect and store rain water. Moisture is taken from these reservoirs which often contain soluble salts necessary for plant life, through scalelike hairs found at the base of the leaves.

in small flower pots which have received a good foundation of potsherds. The ideal soil for them is a mixture of coarse field soil, turfmoss, and decayed wood mold. In the Summer the soil should never become dry, and they must be watered with tepid water.

The large striped *Billbergia* are cultivated in moderately large pots which have been supplied with good drainage. The soil, which should not be too light, consists of a mixture of top soil, hotbed soil, decaying wood mold, and sand. They are to be transplanted either in the Spring, or after they have produced their beautiful but short lived flowers. In Summer they must be protected from the intense rays of the sun, should receive a sufficient quantity of water, much heat, and be placed in well circulated air. They multiply either by division of the roots, or by seeds. In the latter case especially then, when the flowers appear on trailing stalks.

Species of *Hohenbergii* are similarly cultivated but they do not require so much heat.

The varieties of *Tillandsia* are nearly all epiphytic. These plants, in the tropical forests where they occur, attach themselves to the trunks and branches of trees. The most peculiar species of this genus of epiphytes is *Tillandsia usneoides* which closely resembles an herpetic eruption. Roots and leaves are absent, but the epidermis of the long trailing shoots are covered with innumerable minute scalelike hairs which can absorb both the dew and the rain thus supplying the plant with the necessary moisture. Since this plant lacks root it can attach itself to any convenient limb, branch or twig. Even those parts or fragments of this plant which may be torn by the wind and carried away are able to grow and develop into new plants.

Under cultivation these plants require an atmosphere saturated with moisture which can only be given them in a greenhouse or under bell jars similar to those used for the propagation of orchids. Placed in dry air these plants soon wilt.

The larger *Tillandsia* can be placed in a soil similar to that used for the *Billbergia*. Cultivation proceeds as in the last mentioned plant with this addition that the leaves

The roots of *Guzmania mosiaca* are pruned.

A small pot is placed upside down in a larger pot in order to produce rapid drainage.

The majority of the *Bromeliaceæ* can only be kept successfully in greenhouses where the ideal conditions of their habitat can best be imitated, although a few can be kept in the living room. In the Summer these should be placed in the garden where they will be well shaded. Some varieties do well in flat pots or latticed boxes, others again can be attached to the bark of some tree with wire. All pots containing these plants should receive a good foundation of broken potsherds so that the water will run quickly through the root balls. Sand, turf, and charcoal is added to the pots of those plants placed in moss or fern roots. After transplanting, which should take place late in Spring, they should be placed where the temperature ranges anywhere from 60 to 70 degrees F.

These plants should be well watered during the period of their most rapid growth, but toward the Fall, this quantity should be gradually lessened in order to give them a period of comparative rest. In Winter they receive but very little moisture.

All varieties of *Æchmea* are placed in a soil of partly decayed wood or leaf mould mixed with a little sand or moss. These plants should be watered with tepid water. Propagation takes place when shoots appear at the side of the plant.

Species of *Vrisia* are distinguished by their very attractive and decorative variegated foliage. But in order to keep these leaves in good condition they must often be sprayed and washed with a sponge. These plants do well

The plant is imbedded in *Spagnum*.

This moss is then pressed into place with a small stick.

must be sprayed and the plant itself placed in a cool place. After blossoming it should receive less water.

Many species of *Tillandsia can* be attached, together with moss and fern roots, to some rough barked branch or they can be hung in lattice framed boxes which should be surrounded with a glass cage in order to give them a moisture laden atmosphere. They propagate through side shoots which should be left on the plant as long as possible since these are colony forming species. These young shoots should only be removed from the larger plants.

True sons of the soil are the species of *Pitcairnia* which thrive in a mixture of wood mold, leaf mold, hotbed soil, and lawn soil to which a little sand should be added to allow the water to drain off freely. The plants should be placed in diffused light, the direct rays of the sun are injurious. Shoots, which serve to increase this species,

should be removed as soon as they have developed since these only prevent the plant from producing flowers. All species of *Pitcairnia* should be well watered during the Summer months, in Winter they require but little moisture and should be watered accordingly.

Many lovers of plants enjoy placing the tops of pineapples in flower pots where they can easily be cultivated. But before the leafy crown of the pineapple is planted, it should be thoroughly dried to prevent the decay of the leaves. If the top is now planted, the roots will develop with exceeding rapidity. The older plants often produce shoots which are used to propagate this species. If the pineapple is cultivated like other soil *Bromeliaceæ*, it is likely to produce its fruit in the livingroom where its development, before it ripens, can be observed from day to day.

The Flowers of June

FLORUM AMATOR

“THE flowers that bloom in the Spring, tra-la-la” have cast off their pretty gowns and within their ovaries are growing for the perpetuation of their species.

June is now here and June weather, June whose thirty days are the loveliest of all the year, so beautiful indeed as to make us wish there were thirty-one, June of which Lowell says in “The Vision of Sir Launfal”:

“And what is so rare as a day in June?
Then, if ever come perfect days;
Then Heaven tries the earth if it be in tune,
And over it softly her warm ear lays;
Whether we look or whether we listen,
We hear life murmur, or see it glisten;
Every clod feels a stir of might,
An instinct within it that reaches and towers,
And groping blindly above it for light,
Climbs to a soul in grass and flowers.”

Lowell was “country born and bred” and he knew well that the soul of June is grass and flowers and leafy trees, a blue sky and a balmy air and singing birds.

June flowers display a riot of colors and appear in many exquisite forms and exhale delicious odors. We hardly need to remind that June in the North is the month of roses. The Hybrid-Perpetuals this month bloom so profusely that they seem to say to us: “We are going to make such an impression on you by our numbers and beauty that you will remember us till we come again next June.” We do remember them—both their beauty and their fragrance; we have not smelled of a Jacqueminot rose for a year, but we can recall its delicious scent now as we are writing. The climbing roses resting on trellises and pergolas are offering to us their thousands of blooms. The Moss, the *Pernetiana*, the *Polyantha*, the Brier, the *Rugosa*, and the *Wichuriana* roses are contributing their wealth of flowers. The more modest but no less beautiful Tea and Hybrid-Tea are giving their lovely and deliciously scented blooms for June’s Festival of Roses.

Not in a solitary splendor, however, reigns the rose in June; there are other flowers which enter into the lists against her for the prize of the “golden apple,” which a god once offered as the prize for beauty, and upon which, therefore, he caused to be inscribed the word “pulcherrimæ.”

Not all these rivals of the rose can we mention; there are so many. Here are the lilies: “Even Solomon in all

his glory was not arrayed like one of these;” *Lilium candidum*, variously called Madonna, Annunciation and St. Joseph’s Lily, whose sweetly scented flowers are of purest white; *Lilium Canadense*, var. *rubrum* and *flavum*, the red and the yellow Canada Lilies; *Lilium maculatum*, Hanson’s Lily, a stately and handsome species with purple spotted orange flowers; *Lilium puberulum*, the graceful and tall Humboldt’s Lily, whose large golden-yellow flowers are dotted with pale purple; *Lilium Parryi*, considered by some the best of the yellow flowered species, whose flowers are marked with brown. “These are some of the Lilies which June offers us.

The many species and varieties of *Campanula*, the “Bell Flowers,” the “Canterbury Bells” and the Hare Bells hold aloft on their flower stalks bells of blue and white and pink “for verger bees to swing” for June weddings.

The Peonies are a dominant feature in Flora’s kingdom from early to mid-June. This is a glorious flower; no other in its season makes a handsomer or more commanding show in our gardens. In form they present many types, the “Rose,” the “Half-Rose,” the “Japanese,” and so on, and in color they embrace all shades except blue.

For dazzling brilliancy of color no flower in June surpasses the Oriental Poppy, *Papaver orientale*, whose immense orange-scarlet flowers with purple stamens and dark purple eyes are held well up above the foliage on long strong stems for our ardent admiration. There are horticultural varieties of this poppy embracing other colors, but we like the type the best. Like the Peony this poppy is one of the hardiest of all our herbaceous perennials, but is unlike the peony in its habits in that its foliage disappears after its season of bloom, and, being renewed in Autumn, is evergreen through the Winter.

In mid-June the Japanese Iris, *Iris Iavrigata*, the most beautiful of all Irises, begins to unfold its large showy flowers, some single, others double, in shades of color ranging from white to deep purple, and sometimes beautifully veined and mottled. This Iris continues to bloom till mid-July. Massed beside a water course or pond or in the edge of shrubbery, it makes a splendid show and its flowers borne on long erect stalks are excellent for cutting.

Some of the Columbines, Aquilegias, are in bloom this month, both the wild species, *Canadensis*, and the cultivated. We wonder why Harlequin called his love Columbine; was it because she was as uniquely pretty in

form, feature and complexion among women as the Columbine is in form and color among flowers? What is the form of the Columbine blossom, do you ask? We suggest that you get a Columbine bloom and study its form carefully, and then take your pencil and paper and try to describe it for yourself. We ourselves despair of giving such a description of its form as to bring it clearly before the mind's eye of one who has never seen it. *Aquilegia carulca*, the long-spurred Columbine, has large sky-blue flowers; *alba*, a variety of this, has white and *flore pleno*, another variety, double blooms. *Aquilegia chrysantha*, the Golden-Spurred Columbine, bears clear yellow, delicately fragrant flowers. There are several varieties of *A. chrysantha*, some having nearly white and others yellow flowers with red spurs. *A. chrysantha* has a long season of bloom beginning in May and continuing till August. *A. vulgaris* has white flowers, whose incurved spurs are knobbed at their ends; there are varieties of this whose flowers are in several shades of blue and pink.

The *ne plus ultra* blue flower of June is the *Delphinium*, the Perennial Larkspur, of which there are several species and many hybrids. Delphinium flowers are borne on long stalks and are excellent for cutting. For massing against shrubbery and in the border Delphiniums are very effective. *D. Bellodonna* has sky-blue flowers with white centers; *D. formosum* flowers of deep blue with white centers and violet spurs; *D. sinense* flowers of gentian-blue and its variety, *album* pure white flowers. The English hybrid Delphiniums show a range of color from lightest blue to dark purple with white, gray, black and blue centers. The flowers of these hybrids are borne on very tall, branching, erect stems.

Digitalis, whose most common English name is Fox Glove—originally Folk's Glove, that is the "fairy folk"—but which actually has eighteen other common names is an effective June-flowering plant in the border and against shrubbery. Its specific name is *purpurea*, and that of its variety *gloxiniiflora* its varietal name being given it as its flowers resemble in form those of *Gloxinia*.

Digitalis is a biennial rather than a perennial generally, and the best way to treat it is to sow seeds of it every year or to allow some flowers to go to seed and self-sow. The pure white-flowered variety is the most desirable, but purple and pink-flowered blooms also are attractive.

Two species of *Hemerocallis* bloom in June, *H. Middendorffii*, the Yellow Day Lily, whose lily-like flowers are bright yellow and are borne in clusters of two to four on tall erect stalks; *H. flava*, the Lemon Lily, whose fragrant lemon-yellow lily-shaped blooms are carried in clusters of six to eight on upright stalks two feet or more tall. The butterflies and the humming birds call frequently on this Lemon Lily.

Lychnis chalconica, a plant with at least a dozen common names, some of which are Scarlet Cross, Jerusalem Cross and Scarlet Lightning, opens in June its terminal clusters of extremely brilliant scarlet flowers borne on hairy stems two or three feet tall. There is a double form, *flore pleno*, fully as handsome as the species. This *Lychnis*, the petals of whose flowers form a Maltese cross, is perfectly hardy and thrives alike in sun and shade in any good soil. There is another species, *L. viscosa*, var. *splendens*, whose small rosy-red flowers are borne in clusters on stems a foot high. This is called Catchfly, because it has sticky spots on its stems. This resists drought well and is suitable for a rock garden.

Of the June-flowering plants which have daisy-shaped blooms the *Gaillardia* is the most desirable of all. The petals of its large flowers, which are borne on stout stems about two feet high, are at their tips a brilliant yellow, but at their base maroon or red. These flowers are excellent for cutting. *Gaillardias* require free air and full

sunlight and a well-drained soil. They bloom not only through June but continue till heavy frosts come.

Pyrethrum hybridum also has flowers of a daisy-like form, some single, others double with a range of color from pure white to rich crimson; the centers of the single are yellow. The blooms are fine for cutting. *Pyrethrum* requires a well-drained sandy loam, and the full sunlight.

How long, O Flowers of June, would you keep us, if we should speak even briefly of you all? We have mentioned a few of you which we consider most excellent and which we most admire, but we are not unmindful or unappreciative of the more than one hundred others of you which hold up your pretty faces to us, as we walk through garden or field, and fill the air with your sweet odors and contribute your part to June's floral supremacy.

WHAT IS A GARDEN?

(Continued from page 172)

and gardeners call this "accidental" but to me it is the generous gratitude of the garden. Needless to say I shall always try to have them there and probably either fail entirely, or get them glaring red, double varieties.

And so it is. We plan and struggle, we care and tend, but Nature comes along and once destroys, another time assists and teaches us. We put our force and individuality into the garden, and then it asserts its own vigor, and stamps us out.

These are the things that make a garden and put to rout our designs and blueprints. We cannot give our gardens over to chance, and wait for such accidental successes, but we can allow these things a little play. They are always easily enough remedied if they go amiss. They are part of the game and half of the fun. It is the garden's own assertion, its very spirit. Give it a chance.

HOW EVERYONE CAN HELP THE WILD-FLOWERS

The adequate protection of our wild-flowers so that a sufficient supply will be preserved for the enjoyment of future generations depends today on co-operation by everybody. There must be developed a general understanding of what the needs are. Local organizations, where they exist, can answer questions about local needs. Where they do not yet exist, friends of the wild-flowers should combine to organize them. But there are some general rules which should be universally followed. Never gather too many flowers of one kind in the same locality, however common it may appear. Another rule is to pick the rarer perennials with care. If the roots come up easily when you pull them, like those of the blue bells, always use a knife or scissors, so that the plant may come up another year even if you have taken away the source of the seeds. Flowers not perennial, like the fringed gentian, should be picked very sparingly, if at all, because the supply of seeds is the only hope of the colony for the future. Be willing to use occasional complete restraint in the case of especially rare flowers, such as the orchids and the arbutus. Write for general information to the

SOCIETY FOR THE PRESERVATION OF
NATIVE NEW ENGLAND PLANTS,
HORTICULTURAL HALL,
BOSTON, MASS.

OUR COVER ILLUSTRATION

This month's cover illustration is a view of the Wild Flower and Fern Exhibition which was staged at Horticultural Hall, Boston, during May. It shows clearly the artistic and natural arrangement of the unique exhibition which was described in detail in the May GARDENERS' CHRONICLE.

Beautifying Home Surroundings

ARTHUR SMITH

THE next important feature is the lawn, which is in a double sense the groundwork of the garden picture, and a good, open lawn is the natural foundation of a natural landscape.

We emphasize the necessity that the lawn should be a good one, otherwise it will always remain a blot upon the picture, however beautiful the other features may be. A properly made lawn, suitably cared for, will continue a good lawn for all time. It is therefore worth while to construct it right at the outset, as this is the only way to ensure success. We are aware, however, that there are in this country climatic conditions existing which entirely prevent the formation of perennial lawns, and that they have to be sown or otherwise remade, every season.

Speaking generally, with due regard to the fact that every rule has its exceptions, all the center and interior of any constructed landscape should be devoted to open lawn, and in all cases a lawn should be as large and as little interrupted as conditions will permit, with plantings confined to the boundaries.

The actual surface of a lawn should of course be smooth, but it is unnecessary to alter the grade to an absolute level; in fact an undulating or sloping contour is a distinct advantage because it is more natural. Sometimes, to obtain this natural effect, undulations are made, but this requires considerable care so as to avoid the slightest appearance of artificiality.

In connection with lawns of considerable extent, it is permissible to have a few really good trees growing away from the boundary plantings, mainly towards the sides, with one or more about two-thirds of the length of the lawn distant from the house. Trees used for this purpose should be something really worth while and not common-place, and they should have sufficient room not only for the spread of their branches, such spread being invariably equal to the height of the tree, but also to always afford a vista between them. Trees on lawns should not be placed closer than fifty or sixty feet from each other.

It appears, to say the least, somewhat in bad taste to desecrate a lawn with what we term "horticultural monstrosities" like weeping trees, plants trimmed into grotesque or other unnatural shapes, or anything coming under the head of topiary work. We recently saw in the center of a lawn a planting of Privet which is kept trimmed in the form of a couch and two chairs. It is impossible to imagine what beauty can be discovered in this kind of thing; it does not even have the excuse claimed for some garden discords, that it is useful for the purpose which the articles of furniture are made for. Topiary work may be clever and require skill, but those liking it should relegate their collection of furniture, zoological specimens, and other freaks, constructed from living plants, to a place by themselves, entirely shut off from the landscape, as features of this character can never become part of a landscape but only excrescences upon it.

Having the lawn entirely open to the street prevents a garden in its real sense existing at all, as the word garden means "enclosed space." Seclusion and privacy are certainly desirable if only for the purpose of checking the entrance of dust, noise and the smell of combusted gasoline.

Deciduous flowering shrubs are the most important element in boundary plantings, although unfortunately

too many of them contain nothing else. In selecting plants for this purpose, effects for all the year should be provided for. To this end interplanting with some evergreens is conducive, as it will not only increase the color and texture in the Winter, but will also give that feeling of seclusion which is as important at that season as in Summer. Then there are the important points of Autumn colored foliage and berried effects to be provided for during what is sometimes erroneously called the dead season; the latter not only for beauty but to feed the birds.

We have previously called attention to the desirability of lifting our shrubberies out of the region of the commonplace. One may pass many gardens in succession in each of which the planting is confined to the same four or five species of shrubs, such as lilacs, forsythia, snowball, mock orange and deutzia. These are of course all beautiful, and one would not care for a garden entirely without them, at the same time endeavor should be made to do away with the monotony by having something different and making use of some of the less common and rarer subjects.

It is of course impossible, without copying a nursery catalog, to mention all the shrubs which are worth while planting, we therefore confine ourselves to calling attention to a few of those deserving of greater recognition and of more extensive use.

We have always considered that greater appreciation should be accorded to our native plants, more especially when we have to deal with difficult situations in which shrubs and trees indigenous to the locality are certain to be successful. Those members of the *Rhododendron* genus known as Azaleas fit in well with other shrubs. All the native Azaleas are deciduous and are more or less sweet scented and afford a succession of flowers from April to June. Interesting and instructive articles by Frank Meyer upon Rhododendrons are now appearing in this journal which readers will do well to study. The native Viburnums are all good and have the advantage over those known as Snowballs in that they produce beautiful fruit. Others of this genus such as the Japanese *dilatatum* and *Sieboldii* are valuable for the same reason. Another rare shrub, *Symplocos paniculata*, has berries of the exceptional color of lovely turquoise blue.

The Cotoneasters appear to be little known, but they are all pleasing for their flowers and fruit; those which are evergreen are additionally valuable for that reason. Some species of this are less hardy than others. A valuable shrub for its edible fruit is *Eleagnus longipes*. It is also worth planting for the distinct silvery hue of its foliage. There is no genus of shrubs which gives a longer period of beauty in some form or another than *Berberis*, several species of which have some attractive feature in every month of the year. The species best known in the more northern states is *thunbergii*; this is absolutely hardy and should be more used for hedge purposes instead of the more tender and less beautiful Privet. The most beautiful of this genus is *darwinii*, but this unfortunately is not hardy in the north. Among others which are hardy in the latitude of New York may be mentioned, *aristata* with red flowers in June; *amurensis* and *diaphana*, the latter being quite dwarf. *Berberis vulgaris* and its varieties may be left out of consideration, as they are the intermediate hosts to a rust attacking wheat.

In planning for flowers from snow to snow the earliest are given by the native *Benzoin odoriferum*, which adds a second period of brightness in September by its red berries. At the other end of the season in September and October, and sometimes even in November, *Desmodium* and *Vitex* are in evidence; both of these, however, die to the ground during Winter in the more northern states. *Abelia rupestris* has been previously mentioned. Where it is hardy no shrub of medium height is more valuable from the standpoint of flowers only, as it is in bloom from June until killing frost. The native *Hamamelis virginiana* is interesting on account of its flowering stage commencing late in October.

Some other desirable subjects too often conspicuous by their absence are found among *Crataegus*, *Malus*, and *Pyracantha* genera, all of which are desirable both for their flowers and their fruit.

Another native shrub deserving a place in our gardens is the Beach Plum, *Prunus maritima*, well known in some districts along the seacoast. It is especially suitable for dry, sandy places, and is valuable not only for the masses of white flowers in Spring, but also for its fruit, from which the most delicious preserve and jelly can be made. Another native suitable for like conditions is the Bayberry, *Myrica cerifera*, which forms a dense dome, withstanding the salt spray better than anything else. Its berries, from which candles are made, are a pleasing feature of the Winter. This is the plant which one of the speakers at the recent Washington conference upon the Federal Quarantine Law confused with Barberry.

Obviously there is scarcely a garden large enough to plant everything worth while, and in any case, one should make their selection with due regard to the climatic and soil conditions. There are so many perfectly hardy shrubs, able to withstand everything that comes, that the planting of those which require a lot of coddling appears to make for unnecessary labor, especially when the house is occupied all the year round. In the case where the place is only a Summer home, boxing and covering with straw envelopes which always give a suggestion of unnaturalness to the place, and point out that the plants are foreign to the situation, may be carried out for the sake of Summer effects.

While the creation of gardens by the seashore along the more northern Atlantic States presents problems of perhaps more difficulty than any other places, they are not impossible of solution. The first thing one must make up their mind to in this connection is to be content with what will live under the conditions, as failures are invariably brought about by the object lessons plainly set forth by Nature being totally disregarded not only as to the species planted but in the manner of planting and after care.

In situations exposed to strong winds and a salt laden atmosphere the getting of evergreens to live is a matter of some trouble and sometimes said to be impossible. But the trouble will disappear if one will be content with species suitable to the situation and not attempt the impossible with those that are doomed from the outset to fail. As regards evergreens, Nature plants nothing but Pines along the shore and we cannot do better than follow her example. The most reliable are *Pinus rigida*, *thumbergii*, *austriaca*, and *sylvestris*. *Picea pungens* withstands these conditions fairly well but it is waste of time to plant any others of the Spruces.

Where the area of ground will permit the necessity for creating a barrier against persistent salt winds indicates the advisability of first planting a screen of pines. Plant as closely as possible, not only to stop the wind, but so that they may afford each other mutual protection. It

is well to place *Pinus rigida* on the outside towards the sea, with the others towards the interior of the garden. After creating a living wall of this kind around the garden it will then be time enough to consider the use of other subjects in the interior.

As regards shrubs for the seashore, we have mentioned the Bayberry and the Beach Plum. *Rosa rugosa* is also excellent for the situation although it is generally advisable to prune it severely every Spring. Under conditions where the impact of cutting winds upon them is prevented most shrubs hardy in the district will do well around the coast.

The soil conditions by the seashore are invariably dry and sandy, and want of success is frequently entirely caused by the neglect of watering and mulching. The ground between trees and shrubs should always be kept covered with leaves, grass, coarse manure, seaweed, or other similar material, so that the roots may be kept cool and moist during Summer. Nature always mulches.

It is always worth while to have one's garden planned by some one who both knows plants and is acquainted with the conditions under which they are expected to grow, so that only those suitable to the environment may be used.

A Brief Report of the Conference on Quarantine 37 Held in Washington, May 15, 1922, dealing especially with the amateur and scientific case, and with the present situation and outlook.

THE committee was represented at Washington by the chairman, the secretary, Mrs. F. B. Crowninshield as proxy for Mrs. Turnure and as representative of The Garden Club of America, Mr. A. C. Burrage, and Mr. Elisha Hanson, who for some weeks previous had been co-operating with the committee as Washington representative. There were also present in behalf of related interests Mr. Leonard Barron, Editor of *The Garden Magazine*; Mr. Richardson, editor, and Mr. J. J. Lane, manager of *House and Garden*, and Professor E. A. White of the New York State College of Agriculture.

There is much cause for gratification in the fact that Secretary Wallace presided in person throughout almost the entire conference, and that the conference was thrown wide open for the discussion of any phase of the quarantine situation. This made it possible to directly inform the secretary regarding the attitude and objectives of those who criticize Quarantine 37—something that we feel had not been accomplished theretofore.

As a result of Mr. McFarland's presentation of the formal brief (which was essentially that left with Secretary Wallace on January 20, but to which no reply had been received), of two brief but vigorous statements by Mr. Burrage, one of which dealt specifically with the importation of hybrid orchids, and of Mrs. Crowninshield's plea for greater latitude with respect to the importation of small bulbs, it appears that any existing misconceptions have been cleared up, and that the way has been paved for logical and legitimate modification of present obnoxious and unnecessarily severe restrictions, provided Dr. Marlatt's distorted point of view does not dominate the secretary.

Of large significance is the fact that the committee had secured, on the very eve of the conference, from a lawyer who has specialized in the analysis of departmental law and practice, a formal brief or report on the legal status of Quarantine 37 in its relation to the Act of August 20, 1912, under which it was imposed.

This brief declares unequivocally that *Quarantine 37* is illegal in that it exceeds the authority conveyed by the
(Continued on page 182)

Work for the Month in the Garden

SAMUEL GOLDING

AS soon as the first crops are over in the vegetable garden it is of the utmost importance, in the carrying out of any plan of intensive cropping, that they be removed and the space again filled with a successional crop that will mature for Fall or Winter use.

It is contrary to good practice to keep on the land anything after it has ceased to be useful, as it tends to impoverish the soil which is detrimental to the succeeding crops, and with our short growing season we cannot afford to lose time if we expect the best from the garden. It is the aim of good growers to maintain a perfect supply of fresh and tender vegetables throughout the season. This can only be accomplished by frequent sowing from now on.

Constant vigilance must be exercised to keep the plants growing freely, and to ward off the attacks of enemies, both insect and fungoid. Persistent cultivation with adequate irrigation is necessary. The improved tools for cultivation and the various systems for watering which are now on the market are labor saving devices well worth the attention of even the small grower whose space is limited.

State the late peas; if the tall varieties are grown such as the Alderman type, and brush is difficult to procure; coarse chicken wire can be used. This should be fastened up securely to a stout post to prevent sagging and consequent damage by winds or heavy rain when the growth is heavy. If the soil is of a light and sandy texture it will benefit from a good mulch of stable manure. This helps to conserve the moisture and keeps the ground cool, a condition necessary for the perfect growth of peas. If green fly appears spray the vines with Aphine. As soon as the early peas are over remove them and prepare the ground for celery, sweet corn, string beans or small root crops. Plant out celery and give an abundance of water to the earlier planted celery which is now growing apace. Give leeks and onions an occasional soaking of manure water; a little nitrate of soda is an excellent stimulant for them.

Tie up romaine and endive to secure fine blanched hearts; fasten securely the leading shoots of lima beans to the poles, as they are easily broken by wind or rain and plant out late cabbage, cauliflower, etc. Thin out New Zealand spinach, allowing it plenty of room, as it is a rampant grower. Spray the melons, cucumbers, squash and egg plant with Bordeaux mixture to prevent fungoid diseases, and spray the potatoes with Paris green to destroy the bug, and with Bordeaux to prevent blight. Cease cutting asparagus by the end of the month and spray with arsenate of lead to keep the larvæ of the asparagus beetle under control.

Sow more endive and some lettuce early in July: also ruta-baga for Winter, and make the last planting of corn around the 12th to the 18th, for if it is sown later it seldom comes in.

Give the sweet peas a dressing of fertilizer; nitrate and Scotch soot are good, and they should have copious waterings in the evenings during the hot weather. If one grows the bright orange and salmon colors it is necessary to shade them with cheese cloth or other light material if we would have these grand colors at their best, otherwise they are disappointing as the sun

bleaches or scalds them badly. Keep the flowers picked daily. The newly planted Summer bedding will need plenty of water until it has become well established. The tying and staking of plants in the borders will require attention, as this is an important detail which pays to do well. Unwisely staking will spoil the effect of the best arranged borders. The plants should be tied so that they have a graceful and natural appearance.

Where the seed was sown in the borders to bloom in that position they will need thinning, for if this is neglected only a short time, the quality of the bloom suffers. Room should be allowed for reasonable development.

Plant the last batch of gladioli about the end of June, although in some localities they bloom if planted in July.

Finish the planting of dahlias. These do best when grown on a single stem, as they give better bloom and are more easily handled. Before planting, divide the old clump, retaining the tubers which have the most promising eye or growth.

All the more tender and subtropical plants can now be put outdoors without delay.

Sow the seed of biennials such as Foxgloves, Sweet Williams, Canterbury Bells for next Spring's display, and some of the smaller growing species can be sown in July. If seeds of the Aquilegia are sown now they will make nice plants for blooming next May. The long spurred hybrids have a wonderful range of color and their decorative, dainty blooms make them one of the most attractive plants in the garden.

Propagate now the various early phloxes; the pink and white forms of *P. subulata* are very beautiful and showy in the rock garden or borders in early Spring. If cuttings of the lovely blue *P. divaricata Laphamii* are taken as soon as they are fit to propagate, are grown on and wintered in a cold frame, and planted out in the Spring as a groundwork for the yellow Cottage or Breeder tulips it has a very charming effect. This phlox is perfectly hardy but when wintered in a frame as suggested it makes an earlier growth and blooms right for associating with the tulips.

The hardy candytuft, *Iberis semper florens*, *Cerastium tomentosum*, *Aubrieta*, *Nepeta*, *Arabis*, *Alyssum saxatile* are all well known and worthy Spring plants to be increased now.

Remove all seed pods from rhododendrons and lilacs. This will help and encourage the plants to form strong new growth.

After the marvellous beauty of the iris and the exquisite peony comes the queen of the year, the rose, and now its legions of lovers will be anticipating many happy hours with them during the next few fleeting weeks when they are at their best. If we are to have unalloyed pleasure in an abundance and perfection of bloom, constant watching and attention is essential or that arch enemy, the rose bug, will bring ruin to the most choice blooms over night. Several antidotes are recommended to cope with this ravenous pest. Spray with Wilson's O. K. Plant Spray or Melrosine, as these are easy to use, but it is a difficult matter to banish him from the garden. Another source of annoyance is the rose slug worm which seems more abundant than usual this year. This

The Greenhouse, Month to Month

GEORGE F. STEWART

THE greenhouse man must always think ahead. No sooner does Summer arrive than we think of next Winter's flowers and plants, and how a succession can be kept up. The last of June young roses must be planted on the benches, so that when frost comes, a good crop may be had indoors. A good strong loam is what they require to grow in. Add about a third of well-decayed cow manure, and to about twenty shovelful of the mixture, one shovelful of bone meal, also a sprinkling of lime. This ought to carry them well through the hot weather. After the benches have been thoroughly cleaned and washed on the inside with hot lime, about four inches of the compost may be packed firmly all over. The rest of the space should be reserved for future top dressings. The young plants should be planted firmly in the compost and all wires for tying put into place. Keep well watered and syringe on all bright days. Full top ventilation is necessary except when it rains, and then it may be lowered enough to shed the water freely.

Old rose plants may be carried over successfully longer than many believe. We have a fine bench of "Ophelia" in its seventh year, and this year we have as good a crop as ever we have had. However, we never dry them off severely, only enough to dry out the soil well, so that it may be released quite easily from the roots. We leave a nice ball around each plant and clear the rest down to the boards. The leaves are quite green on them, and we cut them back from a foot to fifteen inches high. They always seem to break well all over the plant. We give the same compost to them as to the young plants. They are on their own roots and always throw up well from below to build up the plant. I have come to the conclusion that it is unnecessary to plant young plants often if the old ones are healthy and doing well. We are only going to change this year as we want to try "Mme. Butterfly" instead of "Ophelia."

Young carnations, I believe, are better if planted indoors about the last week in June. They may not appear to make much top during the hot days, but they are making root, and when the cool nights come, they will grow rapidly and will not give short stems in the Fall. My experience has proved that there is little stem rot under the indoor treatment and that insect pests are more easily controlled, in fact, if due care is taken, they may never be seen. A good loam, to which has been added a third of manure, may be lightened with the addition of sand if it is too heavy. I do not like bone meal for carnations but I think they like lime and respond to a good fertilizer, especially when the cool nights come on during the Fall. Let the bud show before they are pinched, as I am sure that they break much better. Give plenty of air, top and bottom, all Summer and moisten the floors and under the benches on all bright days. They should have a good syringing when they require water but let the foliage be dry before night.

Keep begonias growing along into larger pots as they need it. Good loam, decayed cow manure and flaky leaves in equal parts is what they enjoy growing in. A little charcoal is beneficial to keep the soil sweet. A night temperature around 65 degrees should be maintained. Every gardener should try the tuberous rooted *Locotrana* hybrids, if he has a decent greenhouse to

grow them in. There is a wide range of colors among them and they make excellent plants—I saw one last Fall four feet in diameter, which was the finest grown begonia of any kind I had even seen. It was a leaf cutting about one year old. The Lorraine type has been so much grown commercially that many private families are tired of it.

Keep an eye on the young cyclamen plants and do not allow them to get pot bound. They will now do well in a cold frame if bench room in the greenhouse has to be used for something else. Fumigate once a week to make sure that insects are held in check. The mite is very troublesome. An excellent grower told me he kept clear of it by going over his plants every two weeks, washing out the crowns with a nozzle and a gentle spray of water. He said that it was the only sure remedy he had found.

Feed *Amaryllis* plants that have flowered regularly with liquid manure and Clay's fertilizer. A good development of leaves is essential to ensure good flowers next season.

Gloxinias will also take a liberal amount of food to make them flower well. Do not wet the foliage as it is likely to make it spotty. This applies also to *Achimines*.

Chrysanthemum bush plants should now be in their flowering pots and kept well up to the glass to encourage a sturdy growth. See that they are pinched regularly and evenly. Syringe them regularly as red spider is likely to gain a foothold. It is advisable to place a few stakes around them to prevent the shoots from splitting.

It is now time to get a batch of poinsettia cuttings in. Take them off with a heel and pot singly in two-inch pots in equal parts of sand and sphagnum moss. Place them in a tight case and water them every bright day until they show signs of rooting. Air the case out two or three times a day by opening it for a few minutes. By this treatment we hardly ever lose a cutting.

Euphorbia Jacquiniiflora is also a useful plant around December and January and can now be rooted in an ordinarily warm cutting bed. Water it well when it is put in the sand, but allow the sand to become fairly dry between waterings.

Early sown calceolarias, cinerarias, and primulas will now be ready to pot off into small pots. Equal parts of loam, leaf mold, sand, and dried cow manure make a nice compost for first potting. A greenhouse facing north is an ideal place to grow them in all Summer and failing that, a cold frame. Give plenty of air and shade from strong sunlight. Watch carefully for green fly and thrip. Fumigate with Nicofume once a week as a preventative.

All hard wood plants can be plunged outdoors in ashes about July first. On no account let them get too dry at the roots. Syringe them once or twice a day on all bright days and weekly applications of Clay's fertilizer until they set their flower buds will do wonders in keeping them with a nice healthy color, if they are well rooted. Any extra strong shoot which may be outgrowing the others should be pinched to preserve the symmetry of the plant.

Fuchsias and specimen geraniums thrive better outdoors

or on a veranda for the Summer. Geraniums if placed in a sunny position and well fed, will flower all Summer. Fuchsias will stand a little shade and they require stimulants to keep them flowering.

We have a plant of *Kalosanthus coccinea* in flower just at this time. It is a plant that is not seen very often and yet, when in flower, it is one of the most showy. It keeps in good condition when blooming for three weeks. After it has finished flowering, we cut it back about six inches above the pot and do not over water until it breaks, which it does all over the old stem. After it has started well, we repot it in a pot about two inches larger, in equal parts of *Osmunda* fern root, fibery loam, and sand and add a little sheep manure. It is potted firmly and placed in a sunny position outdoors for the Summer. Cuttings may be secured from the old flower stems, which will soon root in sand. Cut them into pieces about an inch and a half long.

Another evergreen shrub flowering now is *Mackayii Bella* with pale blue spotted flowers. It is a handsome evergreen bush and to have it flower successfully, must be subjected to a drying process during the Winter months, when it should show signs of wilting before being watered. It grows vigorously in a strong loam from the time it finishes flowering until Fall, but it requires shading throughout the Summer. After September it stands full sunshine.

Calanthis that is rooting well should be fed with manure water, and nothing is better than cow manure. We use a good handful to a three gallon watering pot once a week. The house they are growing in should be kept rather close and humid with a little fire heat in damp weather.

Cattleyas which are making their growth will demand plenty of water. We find that the best method is to give them a thorough drenching and then allow them to dry out well before repeating. They also respond to soft coal soot water and a light liquid made of hen manure. It should, however, be weak and done with a careful hand. It is quite foolish to think that orchids do not like stimulants; for instance, ask the question: What is the analysis of the compost they are potted in and of the water they are watered with? Do they not secure a great deal of decayed vegetable matter in their native habitat, and manure from winged animals?

Phalenopsis are growing nicely. Watch out for snails which may be in the compost, for they soon destroy the young growths. A little stimulant as advised for cattleyas we find they respond to, but it has to be applied with care. Scale is somewhat troublesome if the sponging of the leaves is neglected.

Odontoglossums which have flowered and need repotting are better off if one waits to do this until the young growth appears. Water them thoroughly whenever they require it. Do not disturb them at the root unless the compost is in a sour condition and there is not room for the young growth to develop. The same applies to Miltonias, except that they require an intermediate temperature.

In the grape houses fruit will be ripening in the earlier houses. Give plenty of top and bottom air to develop the bloom. The later houses will be setting, and some of them will be ready for thinning out. It is essential that the berries have plenty of room for development. Too many bunches should not be left on one vine. After thinning out, an application of Clay's fertilizer or Thomson vine manure will assist in developing the fruit. Point over the borders with a fork occasionally to give the roots a chance to breath air.

A succession of melons should be kept up. Pinch side growths so that they will not overcrowd.

Continue to think ahead, and try to improve on last year's methods.

A BRIEF REPORT OF THE COMMITTEE ON QUARANTINE

(Continued from page 179)

Act. The report made by the Congressional Committee when the act was passed is quoted in obvious support of this contention.

When at the opening of the conference the legal question thus raised was introduced by Mr. McFarland, Secretary Wallace, agreeing that it was not a matter for discussion at a general meeting, also agreed that it ought to be definitely settled, and that opportunity would be given to have it reviewed at a conference at which both sides could be present with counsel. Such a conference was held on May 31 and the Solicitor of the Department now has the matter under consideration. Obviously if the quarantine is found to be illegal there is no object in working for modifications of its regulations until it and they are brought into thorough accord with the law.

On the other hand, pending the settlement of the legal question the secretary has authorized, and the Federal Horticultural Board has agreed to hold, conferences with groups interested in specific modifications. There appears reason to believe that the reasonableness of the demands for at least some of the recommendations made can be proved to the satisfaction of the Federal Horticultural Board. The board having left for California immediately after the conference, further discussion of modifications will be delayed for a few weeks.

This committee will keep you informed of important developments as they occur, or of any need of further active co-operation that may arise. On the whole it feels that from the amateur standpoint the Washington conference was a distinct success in that it—

- (1) Gave all the facts full publicity and brought them to the personal attention of the Secretary of Agriculture;
- (2) Elicited acknowledgment by the Federal Horticultural Board that certain of its rulings have been arbitrary and might suitably be subjected to examination;
- (3) Raised the fundamental question of the legality of Quarantine 37, thus bringing about a definite study of the situation;

(4) Assured the discussion of such matters as the admission of more kinds of bulbs and other plants, the more general issuance of permits to amateurs and other specific recommendations made on May 15;

(5) Gave opportunity for official delegates from England, Belgium and Holland to present admirable arguments in behalf of a broader policy as regards international horticultural trade and reciprocity in international control of plant pests and diseases. The calm and clear statement of Mr. W. G. Lobjoit, head of the government service which protects England adequately against the introduction of plant diseases and insect pests without any of the discriminations, annoyances and hardships of the American practice, was most impressive.

Very truly yours, E. L. D. SEYMOUR,

Secretary Committee on Horticultural Quarantine.
June 3, 1922.

The Plants of Marsh and Moor

WILLARD N. CLUTE

PLANTS, like people, are most interesting when they have done something out of the ordinary. The common plants of our fields and woods lead a somewhat prosaic existence and do not attract particular attention, but when a species has adopted some unusual device to conserve its water supply, to get up to the light, to distribute its seeds, to avoid too much water, or what not, it at once becomes distinguished from its fellows and an object of curiosity. So important is water in influencing plant growth that those species which have to contend with conditions in which there is too much or too little moisture have unusually strong claims to our attention. The desert plants are of perennial interest but many species at the other end of the list, which are rooted in mud or immersed in water, are scarcely less attractive.

When we examine the water plants, however, we find that they are by no means alike in their structure or physical requirements; in fact, there is probably no other large assemblage of plants in which the lines defining the component groups are more sharply drawn. As a good illustration, take the case of the pitcher plant. Everybody knows that this plant grows in wet places, but with no more information than this as a guide, one might search for months without finding a specimen. The plant grows only in a certain kind of wet place and it is useless to look for it elsewhere. For this reason it is often entirely absent from large areas. But when the pitcher plant is once found, there is certain to be found with it a number of other peculiar plants which are its constant companions. Together they make up an association which is always characteristic of certain soils.

The plant groups that inhabit our wet lands are so conspicuous that the common people, without any special knowledge of botany, have distinguished and named the principal forms. The words bog, fen, moor, swamp, and marsh carry with them definite ideas of vegetation and each suggests a different phase of it. The marsh may be said to be the progenitor of all the others. It might be defined as an area that is covered with water for the greater part of the year. Naturally it has fewer species than drier regions, but such forms as find it habitable often occur in immense numbers. Among familiar examples are cat-tails, bulrushes, water arums, pickerel weed, arrow-heads, and coarse sedges. Little by little the marshes fill up, partly with their own plant remains and partly by particles of soil brought in by the rains or blown in by the wind. They then become swamps and ultimately meadows, but not without several changes of plants by the way, in which may be found lilies, orchids, iris, skunk's-cabbage, marsh-marigold, boneset, Joe pye-weed, asters and a host of sedges and grasses.

The marsh, however, does not always become a swamp. Sometimes the vegetation it produces accumulates beneath the water and slowly turns to a brownish mass known as peat. Under such circumstances we are likely to call it a peat-bog, but there are various types of peat-bog as the plant covering of such areas readily shows. If the soil water happens to be alkaline or neutral, the vegetation will resemble that of the ordinary swamp. In this country we do not have a distinctive word for such an area, but in England it is known as a fen. The fen is most frequently found near the mouths of rivers where for any reason the flow of water is obstructed. When cleared and drained the fens are among the most productive of soils.

When the soil water in the bog happens to be acid, a very different, and in many respects remarkable, flora appears. The acid in the water renders absorption difficult and we have what is essentially a desert flora in the midst of water. This is the home of the pitcher-plant, the sundew, the bladderwort, the butterwort and other insect-catching plants. Cranberry vines cover large areas, the buck-bean, the cotton grass, the bog ferns, and the marsh cinquefoil grow in the standing water, lady-slippers, calopogons, arethusas, and other rare orchids rise from the mossy hummocks and the huckleberry, marsh rosemary, leather-leaf and numerous other heaths form dense thickets. In the more open places the characteristic bog-moss, known as *Sphagnum* or peat moss, cover the surface for long distances to the exclusion of everything else. For this reason, such places in Scotland are often known as "mosses." The moss is the most important of the peat-forming plants since it has the ability to grow at the tip though decaying below. The leaf structure is of such a character as to allow it to absorb much water, several times more, in fact, than the best absorbent cotton can take up. *Sphagnum*, because of its absorbent properties, was largely used for surgical dressings during the war and it is the material so commonly used by florists for packing.

In Europe the acid type of bog is often called a moor to distinguish it from the alkaline fen. The moor so frequently mentioned in English literature, however, does not always indicate a peat bog. There are drier areas also underlaid with a kind of peat known as "upland peat" which is acid in reaction and in which may be found a number of the bog plants or their near relations. These are also known as moors. Occasionally they are called high moors to distinguish them from the real or low moors. The high moors are densely populated with species of heath and these long ago gave the name of heath to the region and the name of heathen to the people who inhabited it.

WORK FOR THE MONTH IN THE GARDEN

(Continued from page 180)

attacks the foliage of the plants causing them to burn brown and shrivel. If left alone the slug worm will denude the bushes, and in any case it is very disfiguring and becomes a severe check on the growth. It is often active before preventive measures are taken as it is at first difficult to detect until the foliage shows the work of the pest. Arsenate of lead, O. K. Spray, or a nicotine wash will check it, and these also take care of green fly at the same time.

Keep the privet hedges well sheared and edge up garden and lawn paths and drives. Give cobble gutters and weedy drives a dressing of weed killer. This is best applied after some rain as it is then more effective than when applied in dry sunny weather for it evaporates quickly and does not then penetrate the roots so well and therefore the effects are not so lasting.

The man who thinks he has done everything he can do, has merely stopped thinking. He is what might be called "up and out," and excepting that he has more money, his case is not really very different from that of the man who is "down and out."—*American Magazine*.

More About Budded Versus Own Root Roses

ARTHUR SMITH

I CAN say with absolute sincerity that it was a pleasure to read Mr. Craig's criticisms because I know full well how valuable and worth while his opinions are; because it has always been a matter of regret to me that there is so little discussion in the CHRONICLE connected with the theory and practice of our profession as we can always learn something from each other, and also, as far as I am personally concerned, criticism, however adverse, is always welcome, even if for no other reason than that it shows the critic has done me the honor of reading the article.

Regarding the question at issue, it appears to be that Mr. Craig to some extent misses the main point connected with my statement that, "When a rose is upon its own roots it is less liable to Winter-kill, for if it *should be killed to the ground it will invariably send up new growth from below.*" The main point I wished to make is covered by the words in italics as, while I fully admit that some varieties, especially among Hybrid Teas, do better when grafted, at least for the first year or two, it seems to me that in the case of roses upon their own roots a more or less considerable portion of the rose is under the ground and therefore protected. As Mr. Craig states, burying roses (entirely) gives them protection (in severe climates), therefore he will doubtless admit that when only a portion is buried, as in the cases of roses on their own roots, that portion will receive so much additional protection.

Having practiced gardening for two years in the Berkshire Hills district of Massachusetts, I know something about the New England climate. While I never attempted to grow Hybrid Teas there, I had some Hybrid Perpetuals upon their own roots and wintered them out of doors without loss. As Mr. Craig says, far too many roses are planted too shallow. I believe that when roses on their own roots do die out it is invariably caused by want of drainage, and in this connection am prepared to admit that the *manetti* stock will live in a badly drained soil when an own root rose will die, but neither in this country nor in Britain have I ever known an own root rose to die when the soil has been properly drained.

I know that many thousands of grafted roses are distributed in this country every year, but at the same time there is one old-established nursery firm in my state that, for the reasons I have stated, has for some time ceased sending out grafted Hybrid Teas, and makes a special point in its catalog that *all these roses are upon their own roots.*

Naturally I endorse what Mr. Craig says about roses doing so well in Great Britain, and, while grafting is extensively practised there, "own root enthusiasts" are very prevalent, and William Robinson of that country, whom I venture to think Mr. Craig will admit is no mean authority, in his "English Flower Garden," writes some very severe strictures upon the practice of grafting roses.

I fully agree with Mr. Craig that I ignored a large number of good roses in all classes, principally by reason of the fact that they are too numerous to mention. My prejudice in favor of Paul Neyron is mainly on account of its perfume, as scented roses have during recent years become scarcer in our gardens, and also perhaps because there were so many of this variety in the garden in England where I spent my childhood days.

Damage from mice nesting in strawy manure is invariably caused by its being placed in position too early. This important point was unfortunately omitted from my

article, although I had emphasized it in a previous article on Winter Protection of Hardy Plants. It is not necessary for the good of the roses to put on this mulch until after the ground has become frozen to the depth of an inch, at which time the mice will have taken up their Winter quarters elsewhere.

ANOTHER READER COMMENTS

T. A. Weston

I NOTE that "Florum Amator" in his interesting notes on "Sweet-Scented Flowers" includes the musk, *Mimulus moschatos*. He would confer a favor on many, especially in England, if he could say where there is a strain of seed that will produce scented plants. For the past 20 years or so, scented musk has been a rarity. One may buy musk seed or plants in England, but scented, no; the chance is one in a million and, as a result, the old time demand for musk has vanished. No one can explain why the scent has disappeared.

I was interested, too, in Mr. Craig's remarks on roses. Own root roses with but few exceptions, are utterly useless in England and I venture to believe that the slow development of rose gardens in America in past years was largely due to the policy of selling tiny rooted cuttings. Fifteen or more years ago these tiny scraps were almost the only class offered; good enough perhaps for California, Florida or under glass where growing conditions are regular. But even in such places the budded or grafted plant is the thing in these days; a few firms prior to Quarantine 37 realized this, and made a point of importing English and Irish grown roses.

If there was any question as to the uselessness of tiny own root roses, it has been dispelled in recent years. People will far sooner pay \$1 for one good plant than accept 12 rooted scraps. It is all a question of education.

The so-called hustlers who in past years thought European commercial methods were too slow have been confounded and it is now a case of supplying strong open ground bushes that will flower freely the season of planting. As people become more educated to what quality in plants means, the less opportunity will there be for the speed of merchants to make a living. It is idle to assume that one can get by the customs that have stood the test of time in Europe just because we happen to be in America. Now that perennials have come into their own, the flooding of the country with mediocre stocks of seedlings is not going to satisfy the enthusiast. Named subjects from reputable raisers are what the people of Europe want, and when one sees the goods it is easy to understand. No, sir! real plant lovers want plants that have individuality and quality and are not going to be content with "flopoodle" pansies, pyrethrums, delphiniums and the rest. Quality plants whether seedlings or propagated by other means, are not obtained by factory methods. You have to start off with the real goods and then follow the rules that older folk than we found necessary.

Which reminds me that the N. Y. Agricultural Station has now, after persistent experiments, announced that small potatoes planted whole, are equal or even better than large tubers cut in pieces. While the British and presumably the German have for scores of years followed this practice, we preferred to cut our salable potatoes for planting, despite the knowledge that the average per acre in America and Canada is only half that of Britain and Germany.

ARTIFICIAL FERTILIZERS

Their Use in Spring and Summer.

THERE are still many gardeners who are almost afraid to use artificial fertilizers, and who, in consequence are finding themselves in difficulties owing to the high cost and genuine scarcity of dung, on account of the rapid supersession of horses by machinery. It is for such gardeners that the present article is written, not for the man who has used artificial fertilizers for the last twenty years, for he, of course, will "know all about it."

From this time forward until about the middle of September artificial fertilizers should be in full use. It is often the early and the late applications that count most. Crops can be rushed through a danger period or pushed on to be ready for a certain date. One cannot do this with liquid animal manure whatever anyone may say to the contrary, and one certainly cannot get the beauty of color in either flowers or vegetables without "artificial" that one can with them.

Like almost everything else, artificial fertilizers have been classified and, if I may say so, over-classified. Nearly every garden writer has some pet classification of his own. He either classifies them as regards to the crops that they benefit most, or as regards their solubility in water, or, again, as to the metals of which they are compounds. The present writer would like to abolish all this over-classification, which makes the subject confusing and so often leads to disaster in the case of the inexperienced. Let them be divided into four great groups and stick to that.

The most important group is that of which the principal ingredient is nitrogen. Nitrogenous artificial fertilizers comprise nitrate of soda, sulphate of ammonia, nitrate of ammonia, nitrate of lime and a few others. All are very soluble in water and remarkably quick in action. They produce leafage and nothing else, therefore they should not be used for flowers or vegetables where undue quantities of foliage are undesirable. If, however, crops are wanted to make leaf growth, they should be given nitrogen in one of the forms named above, using it at a rate not greater than one ounce to the gallon of water or half an ounce to the square yard.

The second group is that of potash manures. Potash itself is a metal which few gardeners have seen and none need want to see. Its salts, however, are exceedingly useful; in fact, such crops as potatoes and, indeed, many roots can hardly be grown to perfection without them. Being a metal, potassium combines readily with acids, and one of its compounds, saltpetre, is often used as a nitrogenous manure. In reality, however, it can be used for supplying both potash and nitrogen to the soil, and it will be noticed that it does not make plants "run to leaf" to the same extent as a purely nitrogenous fertilizer. Phosphate of potash is another of its combined salts, but this will be treated in the next section.

Beyond these are two salts of potash for use namely, sulphate of potash and wood ashes, which contain a percentage of carbonate of potash. I need hardly give particulars of the value or use of wood ashes since even the veriest amateur understands it. Sulphate of potash is a valuable fertilizer for application throughout Spring and Summer. It may either be used dry at the rate of one ounce to the square yard or in solution at the rate of 1 ounce per gallon of water.

The third group of artificial fertilizers consists of those supplying phosphates to the land. I have already mentioned phosphate of potash in this connection, but it is not recommendable for general use owing to the difficulty of storing it. It has a disagreeable habit of deliquescing, and must therefore be kept in a damp-proof tin if it is to be stored at all. About a quarter of a pound of phosphate of potash is ample for a ten-gallon cask of water.

Among other phosphatic fertilizers superphosphate of lime is probably the best known, and an effort should be made to obtain a sample with the highest possible percentage of solubility. There is always a considerable amount of superphosphate which will not dissolve, and it is therefore a good plan to make up a stock solution and allow the sediment to settle. If a pound of superphosphate of lime is dissolved in a tub of water holding about eight gallons and then one part of this stock solution used with every two parts of water, a liquid fertilizer quite strong enough for ordinary purposes will be the result. It does not pay to give superphosphate too strong on account of its being a very acid manure. While potash fertilizers increase quality, phosphates induce earliness.

The last group consists of general artificial fertilizers. One of these, which deserves carefully experimenting with, is sulphate of

iron, as it intensifies the color of both flowers and foliage. In large doses it is very poisonous, but I have successfully used it up to about half an ounce to the gallon of water.—*The Garden.*

CLIMBING PLANTS IN HOUSES

THERE are differences of opinion regarding the employment of climbing plants in the greenhouse or the stove, more especially, it must be said, when these climbers are planted with a view to covering, partially or wholly, the roof of the house. Many good plantsmen object to such plants, giving as their reason the fact that climbing plants interfere with the light and make the objects grown beneath them drawn, weakly, and unsatisfactory. Other equally good plantsmen maintain that (especially in lofty houses) the use of climbing plants is effective, and that by the employment of suitable plants for growing beneath them no great difference can be noted between plants grown in partial shade and others grown in a house the roof of which is entirely unobscured. Both schools of thought obtain adherents, but it may be said, as in most cases, that there is a middle way, by following which climbing plants may be cultivated with but little detriment to others grown beneath them. The middle course, naturally, is to plant such things as are not too rampant in growth, and to thin these rather freely when occasion requires. Two plants, formerly popular, may be mentioned as examples of climbers to avoid. These are *Cobæa scandens* and the *Tacsonias* generally. The commoner *Passifloras*, too, might also be classed as objectionable, while, however useful it may be, *Acacia dealbata* might very well be added to the black list. Apart from these, other climbing plants, if judiciously used, need not be tabooed. It is, of course, difficult to decide at what time thinning ought to be done—more especially in early Spring, when some climbers will be coming into bloom, while others are only starting into growth. The most ought to be made of the former, while the latter should receive attention early, so that the young shoots may not be entangled. In training it ought to be remembered that formality is objectionable and not only from a natural point of view, but it is irrational as well. Loose ties and, in some cases, festooning the growths are very much more satisfactory in every other way. When thinning becomes imperative let it be done freely and in anticipation. Above all, and especially in Spring, a close watch should be maintained on climbing plants, so that outbreaks of aphid may be promptly dealt with. Light fumigations are better given on alternate evenings than a heavy dose in one evening. A few plants may be suggested which are not of too rampant growth. For the stove *Passiflora quadrangularis*, *Clerodendron Balfourianum*, and *Thunbergia laurifolia*; for the greenhouse *Lapagerias*, *Abutilon Boule de Neige*, *A. Golden Fleece*, and *A. Sanglant*, *Plumbago capensis* and its white foam, and *Habrothamus (Cestrum) elegans*.—*Gardening Illustrated.*

SOME WEeping TREES

WEeping TREES have considerable decorative value, and for many positions in the garden, where an upright, tall-growing specimen would be out of place, they might with advantage be planted. It is as isolated specimens that trees of pendulous habit look their best, since any overcrowding does not permit of the development of a well-balanced head. Where space has not to be considered, the weeping forms of the Ash, Beech, Lime, Elm, and Birch are worth considering. But the object in view is to point out a few trees for gardens of moderate size. They are mostly flowering trees, suitable for either lawn or shrubbery. Foremost are the flowering Cherries. These are quite hardy, free flowering, and are among the striking features of the month of May. One of the best varieties for the purpose under notice is *Cerasus rosca pendula*, with single rose-colored flowers. Quite as good in every respect is the white-flowered *C. Mahaleb pendula*. Another gorgeous race of Spring-flowering trees is the flowering Crabs. No pen picture can adequately describe the beauty of these, for they are all blossom, and May is the month they are at their best. The best weeping variety is *Pyrus Malus pendula*, "Elise Rathke," and the color of the blossom is pink. *P. salicifolia* is another of unusual charm, owing to the silvery hue of the Willow-like leaves. The Snowdrop tree, *Halesia tetraptera*, with drooping fascicles of white flowers resembling Snowdrops, is also pretty in the shrubbery. For a similar purpose *Cytisus scoparius Andreanus* may be included, the bright golden-yellow flowers, with a reddish-chestnut tinge in the centre, being

conspicuous in June. As a lawn specimen *Siphonia japonica pendula*, with glossy, Acacia-like foliage, and creamy-white flowers, which appear at the end of the shoots, is worthy of note. Laburnums are time-honored favorites, and though there is a weeping form, *L. vulgare pendulum*, the variety *L. Bossi* is quite as attractive, owing to the length of the bright yellow racemes.

In conclusion, a word in favor of weeping Roses may, perhaps, be permitted, for of all ornamental flowering trees they are the handsomest. Budded on tall Briars, they soon make massive heads, and no system of training displays the beautiful trusses of bloom to more advantage. Suitable Ramblers for the purpose include the well-known Hiawatha, Dorothy Perkins, Excelsa, and Mrs. F. W. Field. *Gardeners' Illustrated*.

ROSE GARDENING, by Mary Hampden. Charles Scribner's Sons, New York.

The ardent rosarian ought by all means to possess this newest addition to the big library of his idol, for it tells well not only how to manage roses but also how to enjoy them. Under as many as forty-two chapter headings are treated all possible aspects. But, written by an enthusiastic English woman, it is a book that must be used with caution by the American amateur with even a fair amount of practice and is apt to involve the tyro in regrettable experiences. In the United States of America only in the Puget Sound region can roses be grown as easily as they are grown in England. Many exceptions must consequently be taken to the many long and very interesting lists of varieties with their descriptions. The American fancier furthermore will miss such varieties as Radiance, Red Radiance and General McArthur among those named for bedding; Columbia and several others among those that are "excellent roses for picking"; and Silver Moon among the Hybrid Wichurianas; while it is strange that in a book written by a European no mention is made among the Teas of Lady Plymouth, nor among the Hybrid Multifloras of Caprice Rouge, nor among the fragrant roses of Garbe Rose, perhaps the sweetest smelling of all climbers, nor of Mme. Maurice de Luze as a rose of remarkable fragrance, nor of Mrs. Herbert Hawsmith as having lovely color, nor of Marie Pavio and Orleans as two of the finest Polyanthas.

In the lists there is gratifying accuracy in spelling the names, except that of Dr. Van Fleck lamentably appears for Dr. W. Van Fleet, Anne of Gierstein for Anne of Geierstein, Blanc Double de Combert for Blanc Double de Coubert, and, as in American catalogs all too commonly Gruess an Teplitz for Gruss an Teplitz and Tausendschon for Tausendschoen. The one named here last is repeated in one list under the name of Thousand Beauties, which, of course, is but the translation of its German name.

The advice concerning practical operations is judicious and clearly expressed; it is strange only that the author's experience with suckering has not persuaded her that the plant ought not be set only so deep that the union of a budded rose is just covered. (In connection one wonders that Europeans are so slow to take up with the Japanese *multiflora* as stocks.)

But the work has many redeeming features. The eight colored plates, picturing eighteen important varieties, are more successful than have been most attempts to imitate on paper the rich and rather elusive tints of the double rose. They all prove again, however, that in western Europe the hues of nearly all roses are brighter and more intense than in this country. Particularly commendable are the chapters Briar Roses, The Whims of Roses, Rose Pruning, Disbudding and Feeding Roses, in which are given twenty-five recipes for fertilizing, Watering Roses, and Curing the Ills of Roses, which contains twenty-eight prescriptions.

The book is least satisfactory in treating of garden plans and general arrangement; most of the designs for beds are fantastic and if followed out would involve endless labor in trimming the grass around them.—F. B. M.

THE AMATEUR'S BOOK OF THE DAHLIA, by Mrs. Charles H. Stone. Doubleday, Page and Company, Garden City, N. Y.

In view of the long-time vogue of the *Dahlia* it is strange that not till now has it had consecrated to it a complete and systematically arranged book. Excepting the rose alone no garden flower of greatly diversified form and requiring and deserving so much study and experience in management has been grown by so many amateur gardeners as has the *Dahlia*. At last there has appeared this neatly made volume, excellent in its scholarly grasp of the entire wide field and presenting in nearly ideal form all the phases, historical, esthetic and practical. In an entertaining style, spiced now and then with a little modest humor, are set forth all imaginable topics, including even Dahlia Shows and a well thought out system of the possibilities of profitable new types and methods of propagation, in addition to the professional and amateur methods of the present country.

The well arranged volume ends with a chart in which appear, in alphabetical order, the names of several hundred carefully selected varieties, with a citation of the important points. Con-

venient blank spaces are left for the owner of a copy of the book to insert notes on deserving new varieties which are continuously to be expected by regions almost in the case of a flower so easily and so quickly brought to blossom from seed of its varied and distinct types. These blank spaces might be regarded as a confession of the author's inability to offer lists of recommended varieties that are quite up-to-date and completely satisfying to the more enthusiastic fancier. She has, of course, kept in touch with originators in the various parts of the country, not excepting those of the Pacific coast; but she has found it manifestly impossible to embrace in her work very many of the supremely fine new dahlias raised recently in California. The amateur, for whom the book is written, could wish only that more pictures had been used, particularly colored ones, and that the chart were accompanied by a presentation of the different types in pictorial form.—F. B. M.

FRUIT GROWING, by Benjamin Wallace Douglass. The Bobbs-Merrill Company, Indianapolis.

As it very beginning the book at once inspires confidence by declaring that, as the business of fruit growing is extremely affected by local conditions, as is shown, "the endeavor has been to lay down basic principles upon which the whole business rests; where new methods are mentioned they are based on experiments confined not to a few trees but to some hundreds of acres and over a lot months but years of work." And in keeping with the sense of reliability felt by the reader as he reads is the attractive and entertaining character of the style; it is quite worthy of the Hoosier State which has produced so notable a crop of authors as well as of fruits of the field; nothing could be finer, for example, than the historical sketch that introduces the chapter on Grape Varieties.

Some statements will be found by most readers just a little startling. One is that there can be no such thing as a pedigreed tree, for the "parent" tree produced the fine fruit not because of any inherent quality of the tree itself but because it was planted in a congenial soil, had a congenial climate and was well cared for; a Rambo that produces little knotty, worthless apples may be the parent of a fine Rambo tree just as easily as could a tree that bore only fine fruit. There are wise words about the habit of growth of different varieties of apple trees, about using fillers in planting, about dynamiting before setting the trees—in certain soils and under certain conditions it may be useless and even harmful; about cultivation and mulching—clean cultivation and dust mulching are best, but cultivation should cease by the middle of August and a vigorously growing cover should be over the ground by the middle of October at the latest, while on hills the young orchard should be cultivated as long as possible without too much loss of soil from washing and then seeded to grass or clover so that the mulching material will be grown in the orchard; about fertilizing—as a rule fertilizers applied on orchards in grass give results while they do not give results when applied to cultivated orchards; about pruning—by the time our tree has reached the age it should begin to produce fruit our annual pruning should be reduced to a minimum; about spraying; about harvesting and marketing—the tendency should be toward growing fruit in small orchards to supply local demand, in attractive parcels; about planting large trees—there is no more wicked phrase in horticulture than the nurseryman's alluring "immediate results."—F. B. M.

GARDENING, by A. B. Stout. World Book Company, Yonkers-on-Hudson.

This is an elementary school text treating of the science and art of growing vegetables, designed especially for junior high schools. The subject is developed through a combination of home and school activities and is correlated with other school subjects. The practical directions are full and complete so that the teacher can devote much of his time to the wider aspects of the work and thus make the study of general cultural value. But it is a book to be recommended to the more mature person also who, without having had opportunity to study gardening under instruction, desires to know every detail, from the breeding of plants and the growing of the seed to the gathering and the storing of the crops. The authoritative character of the volume is attested by the fact that the author has been from boyhood a home gardener, has been a teacher in elementary schools, in the high school, in the normal school and in the university and for nearly three years taught gardening to classes of convalescent soldiers and sailors at the New York Botanical Garden, where he is now director of the laboratories; the different parts were carefully examined also, in advance of the publication, by recognized experts and successful gardeners in various parts of the country.

The book is attractive in appearance. The 188 pictures are nearly all from photographs and are unusually instructive, with very few exceptions. Quotations, collectively entitled Garden Lore, emphasize the esthetic and ethical aspects of gardening.—F. B. M.

Boston, Mass.: Robert Cameron, chairman.

THE ANNUAL CONVENTION

The local committees for the convention to be held at Boston, September 12 to 15, are busy laying out an interesting program for the members at large who anticipate attending the 1922 convention in that city. A joint meeting of the convention committees under W. N. Craig, who is the general chairman, will be held this month and a definite program will be agreed upon which will be announced in the July issue of THE GARDENERS' CHRONICLE, together with the hotel that has been selected as the headquarters of the association at the convention, hotel rates, etc., and to whom to apply for reservations.

The members of the association in and around Boston are most enthusiastic to make the 1922 convention, which will be the second N. A. G. convention held in that city, a rousing success to show how the association has progressed since the first Boston convention was held there.

Interesting and instructive trips to inspect the many fine estates and historic landmarks of that part of New England where the convention will be held are being arranged, as well as lively business sessions for the discussion of problems of vital interest to the members of the gardening profession.

N. A. G. ADOPTS GARDENING COURSE

The Board of Trustees and Directors have endorsed the proposed course for training men in the gardening profession to be established at the Massachusetts Agricultural College, Amherst, Mass., under the supervision of a committee of the National Association of Gardeners and the college authorities. It is anticipated that this course will commence with the terms opening this coming September. In accepting this plan the Board of Trustees and Directors was unanimous, as it felt that the National Association of Gardeners was taking a step in the right direction to give men interested in making gardening their life profession an opportunity to gain both a theoretical and practical knowledge of gardening under proper supervision.

The course as proposed is briefly outlined as follows:

Purpose.—The basic idea of this plan is to combine the benefits of scientific college training with practical apprenticeship in gardening under the joint supervision of the Massachusetts Agricultural College and the National Association of Gardeners.

Qualifications.—Pupils must have common school education, reasonable command of the English language, some practical experience in the field of horticulture and show a distinct aptitude for horticultural pursuits.

First term of theoretical instruction comprises 12 weeks beginning late in September.

Second term of theoretical instruction comprises 12 weeks beginning January 1.

Summer season is from April 1 to September 20 and will be spent at a good horticultural establishment where the student will gain practical experience under the joint supervision of the College and Committee of the National Association of Gardeners.

Third term of theoretical instruction comprises 12 weeks and begins late in September.

Fourth term of theoretical instruction comprises 12 weeks beginning January 1.

Fifth term of theoretical instruction begins about the middle of March and covers 12 weeks.

Apprenticeship year.—At the conclusion of the above program the students showing zeal, industry and merit will be placed in a horticultural establishment to gain varied and effective experience under the supervision of the College administration and the National Association of Gardeners. The apprenticeship year will not be less than 12 months.

Examination of students.—At the end of the apprenticeship period an examination in practical and theoretical horticulture will be given.

Students' certificates.—Students who satisfactorily pass the examination will receive suitable certificates from the National Association of Gardeners and the Massachusetts Agricultural College.

THOMAS HATTON

The association deeply regrets that it must announce the sudden death on June 8 of one of its directors, Thomas Hatton, following an operation at the Presbyterian Hospital in New York City. Mr. Hatton had not been in the best of health for the past year but complained of feeling considerably worse three weeks previous to his operation. His death came as a shock to the many friends he had in the gardening profession who regarded him as being in the best of health. For the last seven years Mr. Hatton was superintendent of Sea Acre, New London, Conn., the beautiful estate of Dr. and Mrs. Tracy Farnam, which position he accepted after resigning as superintendent of Greystone, the estate of Mr. Samuel Untermyer, Yonkers, N. Y.

He is survived by Mrs. Hatton, one son and two daughters. Mrs. Hatton and her children have the heartfelt sympathy of the members of the association in their bereavement.

AMONG THE GARDENERS

Word has just reached the Secretary's office that D. L. Mackintosh, of Alpine, N. J., a trustee of the association, met with a serious accident the first part of May when he was run over by an automobile. Mr. Mackintosh was confined to his bed for more than four weeks and is only now able to move about on crutches, and it will be some time before he will be able to go about again. The Secretary's office is sure all the members of the association will indeed be sorry to learn of Mr. Mackintosh's misfortune.

Roderick M. Crocket, who just recently started in business for himself, came to this country in 1908 after serving his apprenticeship in England and was employed by R. & J. Farquhar & Co., Boston, until 1917, when he went with Cadwell & Jones, of Hartford, Conn., for three years. Mr. Crocket returned to Farquhar & Co. in 1920 at the call of the late Mr. John Farquhar to undertake some work, but which did not materialize because of the death of Mr. Farquhar. In May of this year Mr. Crocket resigned his position to engage in business in the horticultural field for himself at Cranford, N. J.

LOCAL SOCIETIES

WESTCHESTER AND FAIRFIELD HORT. SOCIETY

The monthly meeting of the above society was held at Port Chester, May 9. There was a good attendance and a fine lot of exhibits, and the awards were made as follows: 1st prize, James Stuart, 3 pots of calceolarias, also awarded a Culture Certificate; 2nd prize, George Hewitt, pot of *Schizanthus*; 3rd prize, Wm. Smith, vase of antirrhinums. Other exhibits were made by Thos. Ryan, vase of carnations; James Tough, sweet peas; H. F. Bulpitt, tulips; Alex. Smith and Alex. Greig, larkspurs; Thos. Ryan, 3 pots hydrangeas. Vegetables, 1st prize, Thos. Ryan; 2nd prize, James Tough; 3rd prize, H. F. Bulpitt.

Special committees were appointed for the coming flower show to be held in September. Mr. Read of the E. C. Converse Fruit Farms, of Greenwich, Conn., gave an interesting talk on the spraying and pruning of fruits from the commercial grower's point of view, which was well received by those present. Mr. McGregor of the Salarecene Co., Stamford, Conn., and Mr. Morrison of Wilson Plant Oil Co., both gave a short talk to the members. Four petitions for membership were received.

HARRY JONES, Cor. Secy.

SEWICKLEY, PA., DAHLIA SHOW

The Second Annual Dahlia Show to be held under the auspices of the Garden Club of Allegheny County and the Sewickley Horticultural Society will be held September 27-8-9. Last year's show met with such generous support from the public that it has been decided to hold the show for three days instead of two, as last year.

The preliminary schedules have just been issued, and while the number of classes have been considerably reduced, larger displays are called for; in fact the schedule is an ambitious one, and if everything goes well the show will eclipse anything of the kind ever seen in the Pittsburgh district. The Sewickley dahlia growers did themselves great credit last year and certainly intend to go one better this year.

Groups of 100 square feet are called for and one class calls for 50 blooms of 50 varieties, four types and not less than six of a type. Some strong competition is looked for in these classes. Table decorations and other special classes will be provided for in the final schedule.

There are classes for amateurs and the local papers are carrying periodical notes on the culture of dahlias which undoubtedly will stimulate interest among many who hitherto have not thought seriously of growing exhibition flowers.

The planting season is now on and enthusiasm is keen.

Manus Curran, president of the Sewickley Horticultural Society, is chairman of the Show Committee, and John Carman is secretary-treasurer, who together with the various committees, representing the Garden Club of Allegheny County and the Sewickley Horticultural Society are working hard to make the show the success it deserves to be.

WINIFRED N. JONES, Chairman Pub. Com.

CLEVELAND HORT. SOCIETY

The regular monthly meeting was held in the Church of Incarnation, May 11, with R. P. Brydon in the chair. It was decided that the society have a field trip once a month for the next four months to visit the surrounding estates and nurseries.

The Most Greenhouse For the Least Money

Here is what we call our Practical Purpose House.

It will grow exactly as good stock as can be grown in any house, regardless of price.

It is just as free from repairs and will last absolutely as long as the most expensive house we build.

It differs from our regular iron frame private house construction, in having a straight eave instead of a curved one, and an angle Iron Eave Plate instead of a gutter.

The posts extend 2½ feet in the ground and are embedded firmly

in concrete instead of being bolted to a cast-iron sill. This is exactly the way it's done in our largest houses built for the florists where solidity and strength are of greatest importance.

As the posts and not the foundation wall carry the weight, the concrete wall itself extends only six inches instead of 2½ feet below the ground, which considerably reduces reasoning costs.

In short, this Practical Purpose House is the most house that's practical for the least money.

Glad to send you full particulars.

The exhibits of the evening were Darwin tulips grown by F. McNicoll and Fred Heyl. They were exceptionally well grown and caused a good deal of discussion.

A motion to the effect that the June Flower Show should be passed up this year and to hold a chrysanthemum show in the Fall was carried. Two new members were elected.

W. J. BRUCE, Secy.

ST. LOUIS ASSOCIATION OF GARDENERS

The St. Louis Association of Gardeners held its last indoor meeting of the season, in the Forest Park Greenhouses May 3d. This meeting was in memory of Charles Muhlendorfer, a charter member of the association, who died a year ago. Mr. Muhlendorfer in his "last will" donated \$20 to the Gardeners of St. Louis, and this sum was expended for refreshments during the evening. Mr. Muhlendorfer was one of the old-time school of gardeners, having served his apprenticeship in various noted establishments in Germany and France. He was well known among the local craft, and one who never missed a meeting of the association. He was connected with the Park Department of St. Louis for more than fifteen years. Ernest Strehle and the writer related incidents of Mr. Muhlendorfer's life. The evening was pleasantly spent in retrospect and reminiscences.

During the short business session preceding the memorial and social part of the evening the following resolution was passed unanimously:

Whereas, The St. Louis Association of Gardeners are opposed to the wholesale destruction of Redbud (*Cercis canadensis*), and Flowering dogwood (*Cornus florida*), by automobilists and other visitors of the woods, who break the plants to pieces for the sake of the flowers, without considering that by so doing, these charming plants will rapidly disappear from the woodlands near the roadsides throughout the State of Missouri.

Be it therefore Resolved, That the corresponding secretary be instructed to have our protest made public through the press.

L. P. JENSEN, Cor. Secy.

TARRYTOWN HORT. SOCIETY

The May meeting of the above society was held in the Masonic Hall, May 17th, President Wilson presiding, and a large gathering of members present, also a delegation from Westchester and Fairfield Society.

Wm. Scott's prize for best vase of outdoor flowers was won by A. Anderson with a fine display of *Iris*. Very noticeable amongst the other exhibits were several fine plants of *Calceolaria Stewarti*, a fine vase of *Godetia*, also a splendid vase of *Antirrhinum* "Nelrose Pink." A Dahlia show was unanimously decided upon, to be held for the benefit of the Tarrytown Hospital. A committee was appointed to co-operate with Westchester and Fairfield Society to make arrangements for Annual Field Day. James Scott delivered a very interesting talk on the Progressive Age of Horticulture. Mr. Scott laid particular emphasis on the fact that, while great strides have been made with a certain number of plants and flowers, yet there was a great field open, both for new creations and improvement in a great number of flowers, a study which Mr. Scott believes could and should be taken up more by gardeners on private estates. A vote of thanks was extended Mr. Scott upon conclusion.

W. G. WESTON,
Reporting Secretary.

Now—A Power Mower for Medium Sized Lawns

For years Ideal Power Lawn Mowers have been used for taking care of large lawns. The thousands of Ideal Mowers in use have definitely demonstrated their labor saving, money making qualifications.

However, there are thousands of lawns hardly large enough to warrant the purchase of a large power mower, yet with so much grass to cut that proper care becomes a big problem—and an expensive problem.

It was for this vast number of medium sized lawns that the Ideal Junior Power Mower was designed. It is moderate in price, dependable, easy to handle, and costs little to operate.

The Ideal Junior is exactly the right machine for homes with lawns too large to conveniently care for with hand mowers—for mowing the putting greens on golf courses—and for parks and cemeteries as an auxiliary unit

for trimming up and cutting in close quarters.

For Larger Lawns the 30" Ideal Power Lawn Mower

For large estates, municipal parks, cemeteries, golf clubs, schools, colleges, etc., the well known 30" Ideal Power Lawn Mower has no equal. Does the work of 5 to 7 men with hand mowers. Costs about 50 cents a day to operate and soon pays for itself in labor saved.

Furnished with or without riding trailer.

For large parks, golf courses, etc., we build the Ideal Power Triplex Mower.

Write today and get our large pictorial catalog.

GREATER NEWARK DAHLIA AND FLOWER SHOW

The Greater Newark Dahlia and Flower Show will be held at the Robert Treat Hotel, Newark, N. J., September 13, 14, 15. There have already been many entries made from New York, Long Island, Pennsylvania, Connecticut and New Jersey for the commercial, professional and amateur classes. Many garden clubs have taken space, also dahlia societies and commercial dahlia growers. This is the first large dahlia show ever to be held in Newark and it is expected that there will be approximately 50,000 blooms on exhibition. Besides the dahlia exhibits there will be aster, gladiolus, basket effect of roses and little garden exhibits. Schedules are to be had on application from Fred Sachs, who is promoting this enterprise for the welfare of Newark, at the Robert Treat Hotel.

RHODE ISLAND HORT. SOCIETY

The June exhibition of the Rhode Island Horticultural Society will be held in the ball room of the Narraganset Hotel, Providence, R. I., Friday, June 23.

INQUIRY FROM U. S. DEPT. OF AGRICULTURE, BUREAU OF PLANT INDUSTRY

The United States Bureau of Plant Industry, Washington, D. C. Fresh specimens, addressed to this laboratory, should be sent dry and wrapped in paper. FRANK F. SMITH,
Pathologist in Charge.

Some Interesting Facts On Owning Your Own Greenhouse

Every mail brought us such a number of requests concerning the countless things about owning your own greenhouse, that we finally prepared a booklet on just that subject. Furthermore it is called, "Owning Your Own Greenhouse." In it are a goodly number of the less large houses. Many of them are considerably smaller than this one even. Ones that will come well within the means of many who never suspected it.

What is four or five thousand to spend for something that will give you endless satisfaction and untold pleasures *all your life!*

Don't lose sight of the fact that although the flowers are abloom outside now, frost frowns are only a few short months away.

So it's none to soon to start building your greenhouse if you want to have a perpetual summer land of flowers next winter.

Send for the booklet, "Owning Your Own Greenhouse."

THE AMERICAN ROSE SOCIETY

At the executive committee meeting of the American Rose Society it was decided to accept the invitation extended by the Syracuse Rose Society to hold the annual meeting of the American Rose Society in that city, in recognition of Dr. Mills' efforts in establishing rose societies throughout New York State. Upon Mr. J. Horace McFarland's request that he be released as chairman of the membership committee, Mr. Joseph J. Lane, of *House & Garden*, was appointed in his place. The membership now numbers 2,487. President Pyle reported that his firm had propagated 1,700 plants of the Mary Wallace rose for the Department of Agriculture. It was decided to plant out the stock of the Mary Wallace rose thus far propagated so that the dormant plants in two year sizes might be distributed to the firms who will have made application by December 1, 1922. It was further voted that a request should be addressed to the Department of Agriculture to allow the American Rose Society to cooperate in the introduction of other Van Fleet novelties.
Office of the Secretary.

Prepare Now for the Hot Dry Days

No need to worry about the hot, hot, rainless days if you have a Dayton Rotary Oscillating Sprinkler ready. It makes rain when you want it. It sprinkles every foot of ground in a circle or half circle, or 6 feet to 100 feet.

It is better for your lawn and plants and more saving of water than watering with a hose. The Dayton operates on any water pressure from 15 pounds up. If your local dealer cannot supply you, order from us direct. Write to Dayton, Ohio.

City, State

A FEW OUTSTANDING FEATURES OF THIS WELL KNOWN WORK

* Bailey's NEW STANDARD CYCLOPEDIA OF HORTICULTURE contains about 4000 genera, 20,000 species, 40,000 plant names.

* There are 24 colored plates, 96 full page half-tones. More than 4000 engravings which serve as guides in the texts.

* The original color photographs represent many miles of travel.

**OF INTEREST TO COUNTRY
ESTATE OWNERS**

The National Association of Gardeners takes this opportunity to place its Service Bureau at the disposal of owners of country estates when requiring competent gardeners, in the capacities of superintendents, head gardeners or assistant gardeners—thoroughly qualified in every particular to assume the responsibilities the positions call for—gardeners truly efficient in their profession.

The Bureau is maintained entirely at the expense of the association and makes no charge to the employer it may serve or to the member it may benefit.

NATIONAL ASSOCIATION OF GARDENERS

M. C. Ebel, Secretary

286 Fifth Ave. New York

This association is in no sense a trade union organization, but includes in its sustaining membership owners of some of the foremost country estates in America.

SPRAYING

is as

Essential as Fertilizing

Successful cultivation demands a knowledge of the habits of plant insects and diseases, and the proper remedies for their control.

APHINE, an effective remedy against all sap sucking insects infesting flowers, fruits and vegetables, is free of the disagreeable odors and features of most insecticides. It invigorates plant life and is unexcelled as a wash for decorative plants. Aphine will not injure the most tender flower or foliage.

FUNGINE is an excellent remedy for mildew, rust, and other blights. It is readily soluble in water and contains no sediment. Fungine does not stain the foliage but cleanses it.

VERMINE is a soil sterilizer and vermicide. It destroys cut, wire, eel and grub worms, maggots, root lice and ants, and will protect your gardens and lawns from ravages under the soil.

There is but one convincing way for you to become familiar with the merits of these products and that is to try them out for yourself. It will prove worth while.

Sold by dealers in various sizes.

The Davey Tree Expert Co., Inc.
Kent, Ohio.

Gentlemen:

I highly approve of the work done by your men on the trees of the F. O. Lowden estate last year.

Your methods in Tree Surgery are scientific and effectual, and we are entirely satisfied.

Sincerely,

Herman Sanders,

(Gardener F. O. Lowden estate).

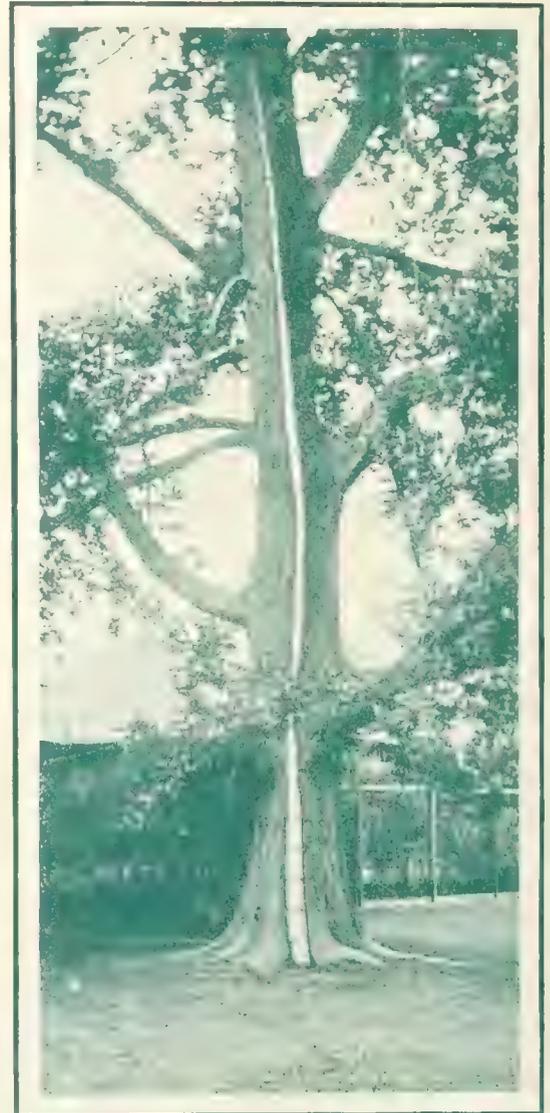

Every gardener and estate superintendent has a most important work in the saving of trees under his care.

Davey Tree Surgery brings to his aid the highest development of science plus a generation of experience. A careful examination of your trees will be made by appointment.

A Million Dollar Business in Saving Trees

By *Martin L. Davey, General Manager*

THE business of The Davey Tree Expert Company is now running at the rate of one million dollars for 1922. It has taken more than twenty years of steady building to reach this volume. The Davey Company sells nothing but service—the service of carefully selected, highly trained, scientifically educated Tree Surgeons, who save trees without guessing or experiment, when they can be saved. This service is available almost everywhere in the eastern half of the United States. Nearly fifteen thousand clients have been served up to this time, many of them regularly.

Lieut. Colonel Frank K. Hyatt, treasurer of the Pennsylvania Military Academy, in a letter written to The Davey Tree Expert Company, December 2, 1921, said:

"Three of your men are performing tree surgery at the college and while I had only engaged them for two days, their work was of such character that I was compelled to hold them longer. In fact, they will probably be with us four or five days.

"They seem to have thorough knowledge of their work and the foreman in charge is a very unusual man. It gives me pleasure to congratulate you on the character of work which your employees are doing."

This letter is typical of many hundreds of voluntary letters of commendation received by the Davey Company from its clients. They come regularly from every section served by Davey Tree Surgeons. It is significant that nearly every letter emphasizes the high type men, their apparent skill and ability to do their work with accuracy and thoroughness and speed, but more particularly the fact that they do their work in a regular and systematic manner.

The evolution of Davey Tree Surgery compared to the automobile

I do not remember to see that ever last client is 100% satisfied. That would be too much to expect from a human organization. But more than 95% of the clients are fully pleased with both the work and the service. Nor would I claim that the Davey organization has always been perfect. It has been a long and hard road, but we have come a long way in the last twenty years.

Davey Tree Surgery has been before the public for more than twenty years. You recall how often it broke down, how many times it was laid up by the roadside?

You remember its imperfect mechanism, its poor lighting, the hard job of cranking? Well, the fundamental principles of the automobile were the same then as now. The wonderful advance has been made in the refinements and the mechanical improvements. Then think of the really marvelous piece of machinery that you buy in the modern automobile!

Just so with Davey Tree Surgery. The fundamental principles were the same fifteen or twenty years ago as today. It was then relatively crude and imperfect. But honest effort and a determined purpose have produced refinements and mechanical improvements and scientific accuracy that are both marvelous and inspiring.

Only two or three men out of a hundred applicants are finally accepted

However, it is the human element of the Davey organization that I wish to describe. The high-type men, their surprising efficiency, their zeal and skill and knowledge are the result of something back behind. That something is a policy that could produce no other result.

From time to time we need additional men. We run advertisements in the cities within a reasonable distance of our headquarters, giving our specifications. Many replies are received. An information blank is sent to each applicant, in which he must give his life history. If a hundred information blanks are returned, our experience has shown that not more than fifty seem to meet our requirements. The others are cast aside.

We then send our representatives to these cities and notify the fifty to report at a certain hotel for personal interviews. Out of the fifty men thus interviewed, we select not more than five who seem to be the right kind.

A regular training field where practical training is given to every man

These five are brought into Kent (Ohio) for practical training, where we maintain a regular training field. These five are put through a thorough course of practical training for several weeks, at the end of which we select not more than two or three as qualified and make up the right staff.

Thus, out of an original hundred definite applicants, we get not more than two or three. The process of selection, though it is severe, works wonders and gives us unusual men for the very important work which we do.

Those who finally pass are sent out into the field, always under the direction of master Tree

Surgeons. They simply get into the work and acquire almost intuitive skill.

A chief expert travels regularly from squad to squad

Then, we have a chief expert who spends all of his time traveling from squad to squad to check up on all the details of the work and the merit of each individual—to see that our high standard is consistently maintained. Occasionally he tells us that a certain man is not our kind and should not be in the Davey organization. That man is promptly dismissed. Very often he tells us that certain men are doing especially fine work and recommends advancement. Such men are promptly advanced.

So the really good men remain with us—and they like their jobs mighty well. Naturally enough, they give superior service.

Constant supervision by local representatives

In addition to this, a number of squads are under the constant supervision of each local representative, of whom we have nearly thirty whose highest self-interest requires watchful care of the interests of each client, to see that he gets the maximum service.

More than this, we require periodic reports on every man in our field force. Our local representatives give detailed monthly reports on the foremen under their supervision. Each foreman gives a monthly report in great detail concerning each man in his squad. Every bit of information from every source about each individual goes into his personal service record. And everyone knows that his service record is complete and strives to keep it good.

The only place in the world where the science of Tree Surgery is taught

When a man in the field force has reached a proper state of development, he is brought into Kent to attend our resident school. This course covers two years—four months each year. We maintain a regular school with complete library and laboratory equipment and a corps of instructors with fine scientific training from various colleges and universities, plus special training in the Davey organization. There is no other school in the world that teaches Tree Surgery, so we maintain the Davey Institute of Tree Surgery as a matter of practical necessity.

In this school we teach only those things required to make real Tree Surgeons—nothing superfluous or unnecessary. The course includes Botany and Dendrology, Pathology and Entomology, Soils and the Feeding of Trees, Spray-

"Do it right or not at all."—JOHN DAVEY

ing and Fruit-growing, and above all the Theory and Practice of Tree Surgery.

Every man in the Davey organization is a trained man—Davey trained

When a man has been with us long enough, has had the necessary amount of complete training, and has demonstrated to us his ability and qualifications, he is entrusted with the handling of operations—then and only then.

Every man in the Davey organization is a trained man—Davey trained. If a man should apply to us for employment and say that he is an expert and understands all phases of the work, recommends himself highly we say to him, if we should happen to need men, "All right, you may start in at the bottom and show us." Very few of them ever come and we are just as well satisfied. Our experience has shown us that not more than one in ten of these so-called tree men from the outside is the right kind of man. None of them are real experts when they come to us. All of them have many things to unlearn.

The Davey Research Department does the experimenting—the client's trees are never experimented upon

In addition to all these other things, we maintain a Research Department in charge of scientists of practical experience. It is their duty to work out every scientific and practical problem of Tree Surgery, as fast as possible. They have done wonderful work. They gather data from every available source, particularly from the experience of the Davey organization, in addition to original experiments. Every experiment is conducted in Kent by our Research Department and never on the trees of a client.

For instance, our Research Department has worked out a list of "forbidden trees," those which experience has demonstrated are not worth complete treatment or do not respond properly to treatment. On these trees our experts are permitted to do only first-aid work.

A national organization that carries with it an assured protection to tree owners

There is no other national organization in our field. There are, of course, many local imitators. It is an unfortunate fact that there are mighty few good ones among them. We would be happy if they were all good and well qualified. But who will supervise them? Who will train them? Who will provide the discipline that will hold them to high-quality service? Who will pass judgment on the results of their work?

There are quite a number, who have never had any contract with the Davey organization, who claim falsely that they are Davey men. There are some, unfortunately, whom we have

been obliged to let go for obvious faults, who attempt to capitalize on the prestige of the Davey name, to our detriment and to that of the profession we have built up and have endeavored to honor.

The unseen things that make quality are only possible because of large volume

In the Davey organization it is the unseen things (rigid selection of men, practical and thorough training, supervision of chief expert and local representative, resident school, research department, standardization of methods and organization discipline) that make real quality and lasting merit. On a business of nearly three-quarters of a million dollars in 1920, we spent three times as much on these unseen things which make quality as we had

in profit. In spite of the depression, we did a business of almost six hundred thousand in 1921 and spent four times as much on these hidden things that make quality as our profit amounted to. The business of the Davey Company is now running at the rate of one million dollars for 1922.

Davey methods have been standardized. Davey work is the same in Boston as it is in Chicago, the same in New York as in Kansas City, the same in Montreal as in New Orleans. Davey experts are of uniformly high type, all thoroughly trained, all carefully selected and developed. And best of all is organization discipline that requires and maintains a constant high standard down to the smallest details of work and service.

A tree-man may fool the public but he cannot fool us

It has seemed to me that the greatest thing the Davey organization does for its clients, over and above all these other things, is that of relieving the client of all worry and responsibility in the selection of the men who are to treat his priceless trees. A tree-man may fool the public, most of whom know little about trees. But he cannot fool us. A man must be right in every sense of the word or he cannot go very far in the Davey organization.

We, who know Tree Surgery values, select the men to whom this work of very great importance is to be entrusted. We know they are right and worthy of your confidence and our confidence or we would not send them to you. They come to you with our seal of approval.

They carry with them the most priceless possession we have—our reputation. We are as jealous of that reputation as a good woman is of her good name. Business and professional success are merely results. The causes are behind the scenes. And that is the reason for this little story of the Davey organization.

THE DAVEY TREE EXPERT CO., Inc.,

Davey Tree Surgeons are near you—if you live between Boston and Kansas City. They are easily available and handle operations of any size, large or small. Write or wire Kent, Ohio, or nearest office.

JOHN DAVEY
Father of Tree Surgery

John Davey gave to the world the science of Tree Surgery. Before the publication of his first book the original "Tree Doctor," not even the idea of the scientific treatment of trees existed. John Davey created the term "Tree Surgery."

Every fundamental principle of it was the product of his genius and love. Every improvement and refinement has been worked out in the organization which he brought into being and inspired. But the greatest contribution which John Davey has made to the world, has been to translate into popular form the fact that the tree is a living, breathing organism.

MARTIN L. DAVEY
General Manager,

who made of a father's dream a business reality and built the Davey organization.

"And yet the tree lives—it breathes. It has a real circulation. The tree digests its food and assimilates it. It has sexual processes that are just as real and beautiful as in any other form of life. It has the power to adapt itself to its environment. To be sure, it lacks intelligence and a nervous system and the power of locomotion. But in all the other elemental processes the tree functions just as truly as man himself."

This question of reforestation is of monumental importance. America can not continue to exist as a virile, forward-moving Nation unless we protect what we have and start to build up that which we have so ruthlessly destroyed. We can not afford to be a Nation of vandals much longer. America must reforest, or America must drink the bitter dregs of national decline and impotency. Excerpts from a speech in Congress, March 3, 1921, by Martin L. Davey, of Ohio.

DAVEY TREE SURGEONS

Every real Davey Tree Surgeon is in the employ of the Davey Tree Expert Co., Inc., and the public is cautioned against those falsely representing themselves. An agreement made with the Davey Company and not with an individual is certain evidence of genuineness. Protect yourself from impostors. If anyone solicits the care of your trees who is not directly in our employ, and claims to be a Davey man, write Headquarters for his record. Save yourself from loss and your trees from harm.

No. 7

The California Garden

ALLISON M. WOODMAN

CALIFORNIA has been called the "land of fruits and flowers," and well may she be given that term, for, traverse the length and breadth of the state, everywhere, verdant plains, meadows, and hillsides will greet one, and orchards filled with blossoming fruit trees will presage future yields of rosy tinted, richly flavored fruits.

California has long been the Mecca for thousands of world tourists who come to visit the beautiful natural parks, to sojourn awhile in her lovely cities, and to enjoy the delightful climate for which the state is so justly celebrated. Many Easterners, enthusiastic over the possibilities of California, decide to dispose of their holdings and to come out to the Coast. Later, after becoming settled, these new residents write back to friends and relatives, resulting in a new influx of settlers.

What are the distinguishing characteristics of the California landscape? First in importance is the wonderful mountain scenery; then in succession magnificent forests containing some of the largest trees in the world, beautiful lakes, rolling foothills, extensive, almost flat valleys, coastal regions. We must also include the many splendid orchards throughout the state, essentially a California product, and which almost seem to form an integral part of the landscape.

California is a land full of scenic wonders; within its confines is to be found every feature of landscape. In these scenic beauties and marvels may be found certain ideas which can find adequate expression in artificial landscape effects.

The Yosemite Valley is to California what the Royal Gorge is to Colorado, or Yellowstone Park is to Wyoming, or the Berkshire Range is to Massachusetts, or the Potomac River is to the District of Columbia. It is an epitome of all that is beautiful and majestic in nature. Small in extent, but bordered by gigantic cliffs that seem to be artificially wrought out of stone, it teems with natural

bits of landscape, park-like in character, and possesses water-falls which for sheer beauty and power have no peer in all the world. In close proximity to Yosemite Valley, and scattered throughout the state, are groves of gigantic Redwoods and Sequoias which are unique among trees.

Wonderful in its setting in Southern California, with Los Angeles as the keystone. The picture presented here is that of snow-capped mountains, bordering a valley, varying in fertility, but made rich and productive through artificial means, offering groves of citrus trees, bearing golden fruits. The flat interior regions merge gradually into the foothills, and from thence into the Sierra Nevada Mountains.

In Central California the cities of San Francisco, Oakland and Berkeley are unique in their commanding outlook over the spacious San Francisco Bay, and in the background of mountains and trees. The moderating influences induced by close proximity to the Pacific Ocean make it possible to produce fine gardens, with flowers blooming the year round.

Northern California presents every variety of landscape from the flat valley of the Sacramento River, and the undulating country bordering the valley, to the densely wooded Sierras on the East, and the Coast Range on the West. In the extreme north Mt. Shasta forms the key to the Sierra Nevada Mountains and the Cascade Range. This sublime mountain, approached by a series of smaller mountains, is almost terrifying in its extreme isolation. Lake Tahoe, near the Nevada state line,

views with the Yosemite Valley in popularity.

Coupled with this diversified landscape is the fact that California possesses every variety of climate, although the climate usually associated with California is that of a mild equable nature, with no marked seasonal changes, but with a distinct period of rainfall. The Summer season

All sorts of rock plants find a haven on this rock stairway.

merges into Autumn with scarcely a perceptible break; the Winter season may or may not be severe; the change from Winter to Spring is gradual; in regions along the coast there is little difference between Spring and Summer temperatures. The interest aroused in the East by the everchanging seasons is compensated for in California by the wealth of flora that persists in the green state all the year.

Two factors contributing to such favorable climatic

This pergola stands at one end of a knoll overlooking San Francisco Bay and the Golden Gate.

conditions, and affecting a considerable percentage of the population of California, are these: Close proximity to the Pacific Ocean, giving a good part of the state somewhat of an insular climate; mountain barriers on the eastern and western borders, deflecting cold polar winds.

Many new residents from the East find it difficult to become accustomed to the flora, radically different in many respects from the flora of the East. The dry turf during the Summer season is also distressing to some, but, whereas a green turf is characteristic of the East, California can revel in the golden brown turf, which furnishes an effective contrast to the dark green of the Evergreens.

The true Californian revels in the brown Summer covering of the hills, which may be destitute of trees, or with a few oaks clustered in a narrow ravine. On the other hand, the Easterner is transported in the sight of magnificent elms, maples, oaks, and other deciduous trees, which could find no other suitable setting than a green turf.

California has been spoken of as "one vast flower garden." This is true in one sense, for there are thousands of native species scattered throughout the state, but it is untrue that the whole of California is ablaze with color. Frequently, the most settled parts are deficient in native flora, and must rely on the importations of exotic trees or shrubs, or the utilization of native stuff from other parts of the state. Due to the benign climate of most of California, it is possible to grow every kind of flower outdoors.

It is of primary importance, before planting a garden, to investigate the flora of a particular region or of the immediate vicinity, and let that form the basis for any future plantings. Failing this, introduced types of trees and shrubs, harmonizing with the native flora, and adapting themselves to local conditions, may be used.

Of all our native trees the oak, and particularly the Live Oak, known botanically as *Quercus agrifolia*, is held in almost a spirit of veneration in the hearts of Californians. There is something so distinctive in the form of the Live Oak, and something so attractive in the contour of its branches, which distinguishes it from all other members of the same genus and from unrelated types. The rich, dense, olive-green foliage affords a wonderful contrast to the golden turf beneath in Summer, while the eye is bewildered by the intricate and graceful curving of the trunk and branches. The Live Oak loves to nestle in glens and ravines, but feels somewhat out of place in broad, open valleys. It forms a delightful setting for a home, and is often used as a basis for laying out estates, especially in hilly regions of cities and towns.

Native trees and shrubs which will harmonize with the Live Oak are: the California Bay Laurel, the California Cherry, the Catalina Cherry, the Madrone, Manzanita, the Toyon or Christmas Berry with its crimson berries, the Catalina Ironwood, and the Santa Barbara or Matilija Poppy. Some of these are often found growing with the Live Oak.

The Redwood, too, a species of *Sequoia*, possesses certain characteristics which distinguish it from all other trees. Going through a redwood forest one experiences a sort of ethereal feeling as a shaft of light pierces through the delicate, arabesque-like tracery of leaves and branches, and break into myriads of blotches of light and shade. Its near relative, the California Big Tree is also distinctive.

What constitutes the California garden as distinguished from the Eastern type of garden? There is a distinct charm about the old New England garden, full of trim little paths laid out in regular fashion, seats, trellises, arches and arbors in set places, garden plots filled with sweet-scented, old-fashioned flowers which is not difficult

A bit of characteristic California scenery.

to feel. So is the beauty of the formal garden felt, so prevalent in certain parts of the East.

It is freedom from conventionality, rather than freedom from restraint, that characterizes all true Californians. It is this spirit which is reflected in California gardens. In the extreme East the spirit which prevails is that of "you must do this and you mustn't do that; observe all of the proprieties; do not deviate an inch from the accepted line of traditional conduct." Here in the West we are tempted to go to the other extreme—to break away entirely from established precedent and custom. But there is an obvious danger in this attitude, which must be guarded against in matters of gardening.

In California, therefore, the trend is towards a distinct informality in most of the plantings. And yet, even in informality there must be some semblance of unity of purpose and conception—in fact, it is really much more difficult to form an informal or naturalistic garden, than it

is to construct a formal garden. Sometimes the wisest procedure seems to be to strike a happy medium between the two—to include the best features of the formal garden, giving them an intimate setting. In other words, we remove the austerity of too formal a treatment, by adding a touch here and there of informality.

It is conceivable that California will some day develop a style of landscape gardening peculiarly her own. In the California garden will be revealed the spirit of the California landscape, coupled with an expression of the feelings and sentiment of the true Californian. Ideas borrowed from styles of gardening in vogue in other regions, which can be utilized to advantage, will be incorporated in the garden, but certain features of the garden will breathe the atmosphere of California.

The illustration on the front cover shows the century-old live oaks (*Quercus agrifolia*) on the campus of the University of California, Berkeley.

Bark and Its Uses

WILLARD N. CLUTE

ALL plants, save the very simplest, are protected from the external world by a resistant covering commonly known as bark. This might be truthfully described as the plant's skin for like the skin of animals, it is renewed from a softer underlying tissue and is constantly thrown off or worn away from the surface. In both animals and plants the outermost layer is known as the epidermis, but the deeper layers, especially in plants, have different names.

Bark is commonly formed by two different layers of growing cells known as cambium cells. The activities of the outer layer produce the corky bark while a deeper layer gives rise to the other tissues associated with the cork cells. This latter layer has a second important function for, in addition to building up the bark, it annually adds a new layer to the woody cylinder. The patterns of the bark, which alone are often sufficient to identify the species, are due to peculiarities in the growth of the cork cambium, but it is the ever-increasing pressure from the growing cylinder of wood that causes the bark to crack along the lines marked out by the cork cambium. Thus is produced the papery bark of the birch, the splintery bark of the hickory, the flaky bark of the sycamore and the furrowed bark of walnut and oak.

In most woody plants the layer of cork is spread rather uniformly over the stem, but in the sweet gum and in some species of the elm and *euonymus*, certain regions of the cork cambium are more active than others and this results in a number of cork ridges or wings running lengthwise of the stem. In the cork oak, the corky bark is so well developed that it forms a layer several inches thick. If this is carefully removed, the cork cambium will produce a new layer of cork in a few seasons. All our bottle corks are derived from this source. The dark streaks seen in the corks are openings through which the living cells transpire. On young twigs these openings appear as tiny specks or lenticels.

The cork cells not only protect the plant from mechanical injury and the attacks of fungi, but owing to the minute air spaces they contain, they also modify the effects of sudden changes of temperature which are so trying to plants. The inner layers of bark are composed of strong fibers, known as phloem or bast. From these fibers is sprung most of the thread, twine and cordage

used for a multitude of purposes in the commercial world.

It is well known that if a ring of bark is removed from a stem the stem dies, but this is not due, as so many assume, to shutting off the water supply of the plant. It is true that there are a series of small tubes in the bark, but these do not carry water and food materials upward. Instead they carry the food elaborated in the leaves to all parts of the plant. Removing a ring of bark from the stem, therefore, stops the supply of food to the roots and the plant slowly starves to death. That food is carried downward in the bark is apparent when one notices how greatly the stem is swelled above any constriction about it. In plants like the grape where the fruiting branches are renewed annually, the branches are sometimes ringed to prevent the escape of the manufactured food which thus remains to increase the size of the fruit.

Although we commonly give more thought to the wood of plants than to the bark, the latter is of such great importance that it may be questioned which is the more valuable. The bark seems to be a favorite place for storing elaborated materials by the plant. In many cases these are in the nature of waste products so far as vegetation is concerned, but they find a wide use in human economy. From the milky juice or latex in the bark of numerous tropical trees and vines most of the rubber and gutta-percha is obtained. A still larger number in all parts of the world yield the tannins so useful in turning hides into leather. Fixed oils are rarely obtained from barks, but there is a long list of essential oils derived from this tissue, familiar instances of which are the oils of cinnamon, sassafras and birch. A large number of the alkaloids and related substances used in medicine are also taken from barks, quinine, is possibly the best known of these substances. In addition there are produced from barks, numerous dyes, gums, varnishes and other substances that are found useful wherever the arts of man flourish.

Think about yourselves, about what *you* want, what *you* like, what respect people ought to pay to *you*, what people think of *you*, and then to you nothing will be pure. May God keep our hearts pure from that selfishness which is the root of all sin!—Charles Kingsley.

Opuntia—Indian Fig

RICHARD ROTHE

Of the hardy *Cacti* known to endure the severest of our Middle Atlantic Winters by far the most are natives of our country. Of the genus *Opuntia* the species: *arenaria*, *camanchica*, *fragilis*, *mesacantha*, *phacantha* and *polyacantha* are all well known to botanists and collectors. Abounding within the mountain regions of Central Colorado they are reported nestling along dry sunny slopes of upward of 5,000 feet altitude noted for minimum temperatures as low as 20 degrees below zero.

Under cultivation they require an open sunny exposure in well drained or outright dry ground. According to popular belief *Opuntias*—or, as they are also called, prickly pears—grow among rocks in the poorest soil imaginable. In reality, however, they need a fair amount and depth of decidedly fertile soil containing humus of a

Opuntia Rafinesquei.

coarse texture for rapid normal growth and free flowering.

Hardy *Opuntias* prove valuable subjects for dry-walls facing south. In rockgarden arrangements we reserve arid slopes facing south and southwest for plantations of the hardy Indian Fig *Cacti* and subsequently enjoy their add picturesque evergreen forms and their abundance of attractive yellow flowers during the early Summer months.

Of the few species listed by the trade *Opuntia Rafinesquei* is the best known. Being a rapid grower of remarkably free flowering habit producing its large deep sulphur-yellow blossoms during June and early July plantations of adequate size add in maintaining a vivid color effect of a rockery at a time when the climax of the vernal glory is past.

All the Indian Fig *Cacti* may be easily propagated by inserting cuttings of the flat compressed branches into sand or light soil. Beware of numerous little spines at the joints when handling cuttings. Winter covering, even in Northern States, should be of a nature allowing free access of air to plantations.

SCENTED MIMULUS MOSCHATOS

Florum Amator Replies to T. A. Weston

Wrote in the June issue of THE GARDENER'S CHRONICLE OF AMERICA, T. A. Weston's courteous criticism as our listing of *Mimulus moschatos* as a scented

plant in our article on "Sweet Scented Flowers."

It was the Roman poet Horace, if we remember correctly, who wrote: "A critic is a whetstone upon which others may sharpen their wits." Far be it from us to fail to embrace the lessons to be learned from fair-minded, intelligent criticism, or in other words to sharpen our wits upon its whetstone.

We welcome T. A. Weston's criticism for two reasons, first because it will lead us to take a strong sniff of whatever *Mimulus moschatos* plants we see hereafter, and secondly because, we have the pleasure of telling Mr. Weston where he and all other good Englishmen either this or the other side of the Atlantic, and Americans, too, apparently can buy seed of the *Scented Mimulus moschatos*. In that comprehensive and reliable, we think, catalog of Watkins & Simpson, Ltd., London, 1922, page 55, we read under seeds:

"*Mimulus moschatos* (musk)
Mimulus moschatos
True Sweet Scented."

All other English and American catalogs at hand say simply *Mimulus moschatos* (Musk), but in *Gray's New Manual of Botany* revised by Robinson & Fernald we read on page 724 the following description of this plant: "*Mimulus moschatos*, Musk Flower, Villous and Viscid, musk-scented, damp soil, Newfoundland to N. Y., E. Pa., Ont., and Mich., abundant in Rocky Mountains whence perhaps introduced."

Perhaps T. A. Weston has not been this side of the "Pond" long enough, or even if so, has been too busy a man with his pen and his beloved New Jersey garden to smell of such musk plants—no runout British type—as Prof. Gray describes.

Mr. Weston's criticism brings into our mind two questions, which I doubt not will interest him as well as *Florum Amator*, namely: Does a scented plant, whether the scent is pleasant or disagreeable become in one year or a hundred years or a thousand, scentless? Secondly—Is it possible there is now and always has been a *Mimulus moschatos* entirely devoid of scent, and a *Mimulus moschatos odorata* which is now, and ever has been scented?

T. A. WESTON ON BUDDED VERSUS OWN ROOT ROSES

JUST a note *re* those roses. Arthur Smith talks of grafted plants, and Mr. Craig, like myself, is probably talking of budded plants. There is a vast deal of difference between grafting and budding. The bulk of the roses raised in Europe are field-budded; only those growers who have glass and who want to make the most of novelties do inside grafting, unless one excepts the French, who do a big lot of dormant grafting during the Winter, and plant the stocks in the Spring.

Grafts do not average so good a union as buds. Budding is the practice adopted in California and New Jersey by those firms who are catering to the demand for good field-grown roses. Deep planting of budded roses does not necessarily mean rooting above the union. I have always made it a practice to lift dwarf roses every two or three years, but rarely have I found roots above the bud.

I might add that last Winter my H. T.'s had no protection whatever, not even earthed up; only one died and that because it was walked upon when under snow.

Better Sweet Peas

CHARLES ELLIOTT

IT is my intention to confine my remarks to up-to-date exhibition culture as I believe that, whether a person wishes to exhibit or to have flowers for table decoration, the highest form of culture gives the best returns. I contend that it is better to have a few good long-stemmed flowers than a wheelbarrow full of poor, short-stemmed stuff.

I am sometimes asked what is the best soil to grow sweet peas in. If I could answer, it would not benefit anyone, but I will try in as brief a space as possible to tell you how to prepare the soil you have, in order to grow sweet peas to perfection.

To grow sweet peas, or for that matter any other crop, good drainage must be secured and I believe most of our gardens are improved by tile draining or some other form of drainage that will carry surplus water away freely.

The site on which you wish to plant should be chosen the previous Fall and spading operations commenced as early as possible. If you have a light soil with good drainage, spade the soil not less than two feet, three will do better, and work into the soil plenty of well-decayed manure, cow manure may be the best, but horse or pig manure will do very well, providing it is well rotted, and in this case you would do well to mix the manure through the soil so that when the roots descend they will find a steady form of diet, and are not gorging one week and starving the next. Always be careful not to have fresh manure nearer the surface than ten inches, and if the soil is not too wet tramp it back into place as the work proceeds. Right here I want to emphasize the value of firm soil, for the firmer the soil, other things being equal, the better the results. Sweet peas cannot be grown to perfection in a loose soil. A good dusting of bonemeal may be added, and the ground should be left rough at the surface.

A heavy clay, as many of us have to contend with, is a difficult proposition, but it will grow fine peas if handled right. It calls for more labor and good judgment, but I believe we like it better in the end.

We have a very heavy soil at Park Ridge and prepare it in this manner: As early as possible we haul onto the site a good dressing of rotten manure and gather all we possibly can in the way of partly decayed leaves and rough garden refuse, and commence to thoroughly trench the whole breadth of the plot which we intend to plant to sweet peas. At the bottom of the trench we place a thick layer of coarse material, such as the decayed leaves, or refuse of some kind, and then, after putting on a layer of soil, spread in a layer of manure, taking care to keep the manure well down, and then some good soil on top, in which to plant when the time comes. We add a good dose of bone, but I do not believe in overdoing the manuring as it may easily cause trouble, and neither do I believe in digging a trench two or three feet wide and as many deep and filling it up with rich earth and manure. I admit good peas are sometimes grown that way, but it is inviting defeat, for such a trench provides a catchpit for a heavy downpour of rain in the hot months, and when this mass gets saturated, it results in the failure of a good crop of sweet peas. Such a trench is also continually sinking during the Summer, the cracks from the sides breaking the feeding roots and causing the whole thing to collapse. This work of preparing the ground should be done early in the Fall in order to give the soil a good chance to become settled before Winter. If any old mortar rubbish is to be had, we work this in the ground and spread some

on top, but failing this we give a sprinkling of some form of lime, and before the ground freezes, if it is not too wet, we arrange the surface into ridges resembling small potato ridges and leave them that way through the Winter. Any time during the Winter months that we have any light material to dispose of, it is spread over the ridges. These ridges break down in fine shape in Spring, and about the end of March we usually have an opportunity to work over the surface, but before doing so, we give the ground a good dusting of superphosphate and a preparation known as Lime Fertile. These are worked into the surface, which is left level and *not* raked. Care must be exercised when the ground is finally finished off not to have a low spot or basin left, otherwise this will prove a catch-basin in times of rain and the rich soil will sour and cause the plants to sicken.

Selection of varieties and raising plants. Generally speaking, growers buy too many varieties and not enough of one variety to assure success. I have noticed that the most successful exhibitors order a large quantity of not too many varieties and stake all on having plenty of plants of each. The exhibitors also generally secure enough plants so that they can select the best for their purpose, and discard the poorest. The logic of this should be plain to everyone. I believe that fifteen to eighteen proved varieties are sufficient for a grower to meet all demands, and to these varieties may be added the cream of the novelties.

There are two methods in common practice regarding sowing seeds and raising plants: Sowing in the Fall, and sowing in the early Spring, in both cases under glass. Fall-sown plants are Wintered in cold frames, the early Spring sowing is raised in heated structures.

For many seasons we have been raising a large number of varieties, some of them choice seedlings worth their weight in gold, and we have found that the method outlined as follows gives the best results in germination and at least as good results in sturdy plants:

We take ordinary flats and fill with fairly good soil to the level, with a good dash of sand, and press this well along the edges with the fingers. The surface is then leveled and the seeds placed an inch or two apart over it. If we have a few seeds of some varieties, we draw a drill with finger tip and sow in it, and when sown cover the seeds well with light soil. By covering I do not mean a half inch, but that the seeds are hidden, which is enough. We then press the whole down very firmly, putting all our weight on the board used for this purpose. The flats are then piled one on the other in a corner of the greenhouse away from the sun and heat of the pipes. The soil should be of about the same degree of moisture as used for potting; wet enough to form a loose ball, dry enough to break apart when touched. Under good management the flats do not require water until after germination commences. After a few days the flats in the pile are looked over, the top flat being placed at the bottom and water being given if there is lack of moisture. Sowing in regular seed pans answers the same purpose, but the center of a three-inch pot is about the worst place I know of to place a sweet pea seed, and I know seedsmen who are looking, club in hand, for the man who discovered the sowing-in-sand idea.

It is generally conceded that the white-seeded varieties give poor results, but I myself find no difficulty, the most difficult varieties being the pink and rose colored. They germinate slowly, but the difficulty is well overcome by chipping a small piece of the hard skin in order to allow

the moisture access. I have had men tell me that life is too short in which to do such things, but I am willing to demonstrate to anyone that these seeds can be chipped at the rate of more than 500 an hour, and I could recite many instances in which it has paid well to take the trouble.

Fall sowing is done around October 15, and when the seedlings are well up the flats are transferred to a cold frame. Spring sowing is done from January 15 to February 15 and the grower must be guided regarding the time, in accordance to the accommodation he has to take care of the plants. It is poor policy to sow early and to have to keep the plants for weeks in a high temperature, but if a cool house is available for the plants, an early sowing gives the best results. The plants are potted on into pots or transplanted into deep flats of good soil, kept near the glass, and given such treatment as will produce sturdy stock.

I want to especially recommend the Fall sowing, and especially to those who have no glass at their disposal. Anyone with a few old sashes, or new ones for that matter, can have as good, and in some cases better, flowers than his neighbor with glass.

Seeds are sown after the middle of October as before described and the plants are given as much air as possible in the Fall months in order to make them strong and sturdy, and when Winter approaches they are placed in a good pit 12 inches below the glass and boards. Straw or leaves should be handy for their protection. They should not be left to become badly frozen, but should be afforded ventilation on all possible occasions, taking care that they are not exposed to a cold wind or to bright sunshine if they have been frozen. Some time during February the plants are transplanted into fresh soil, either in pots or deep flats. I mention the flats because as good or better plants can be raised in flats. The sweet pea is much more adaptable to different methods than many experts would have us believe, and the finest plants and flowers I ever had were raised just as I have described, and anyone possessing the "go ahead" enough to use this method will be well repaid.

If pots are used, the plants usually need a four-inch pot toward Spring, as they grow like weeds when the weather becomes warm, and consequently they must be given all the air and light possible in mild weather. The sash should be removed when the weather permits in order to keep the plants sturdy.

Spring-sown plants must also be hardened off in the same manner before being planted out.

Some kind of support is usually needed for the plants while in pots or flats, and for large plants in pots and flats twigs are the best to use, but for small pots we use a wire coil.

Planting out takes place the middle of April or as early afterwards as weather and soil conditions permit. We always have a double row, or, in other words, two rows fifteen to eighteen inches apart, with an intervening space of not less than six feet from the next double row. We try to have the trellis in place before planting if possible. We also try to have on hand some dry material from the compost pile or old hotbed in order to get the surface of the ground in condition to plant.

The plants are planted six, nine, twelve or eighteen inches apart in the row, according to the vigor of the variety or the strength of the plants. The plants from pots should have the roots loosened around the ball, and a hole large enough to have the roots spread out must be made. In planting from flats we first loosen the whole mass by jarring the end of the flat on the ground, then pry off one side and slide the whole out on the ground. The plants are then separated, an effort being made to

preserve the long roots rather than to try to retain the soil on them. A very good plan is to open a small trench, in the manner that some gardeners plant potatoes, arranging the plants along this trench, spreading out the roots, about half filling the trench with soil, trampling firm, giving a little water, and then raking the trench full.

It is a good plan to provide a wide board to walk on during the planting operation, and to stand the board on edge along the side of the row for a few days to break the wind. At this time the plants must have some support, otherwise the wind will twirl them around on the ground and they will suffer considerably.

The finest exhibition flowers are grown on what is called the cordon system, and the best supports to use in this instance are cane stakes six to eight feet long. I will now try to explain the way we arrange these stakes to the best advantage. A long stout post is placed at each end of the row, securely braced, and two No. 9 wires are run, five feet above the ground, from post to post and drawn tight and held 10 or 12 inches apart by means of short pieces of 1x2; the stakes are then inserted in the soil a few inches deep, and six inches apart, along each side of the double row. They are then tied to the overhead wire six inches apart. At the bottom of the stakes the rows are 18 inches apart, but the overhead wires, being only 10 or 12 inches, cause the stakes when tied to it to lean in at the top from either side. The advantages of this arrangement I will enumerate to you.

From the beginning a single stem is taken up each stake and, because each stake leans inwardly, the growths naturally come to the outside of the trellis, and thus it is easier to tie the growths to the stakes, and they present a much better appearance as the outside of the stakes are covered. But what is still more advantageous is the fact that the flower stems when they appear, instead of following the course of the vine, stand directly up and out away from the vines, thus having a better chance to develop, and there is less chance for the stems to become damaged through whipping against the trellis. Another thing, it is a very easy matter to gather the flower stems. You all remember how the best flowers always get entangled in the vines when they are grown on any other trellis. Some growers use two by four posts and nail 1x2 overhead to which the stakes are tied, but I think the wires look better, and it is also more safe with the cordon system. The advantage of having the stakes so wide apart at the base is that a man can take a hoe or hand cultivator and, by walking backwards, cultivate the space between the stakes with ease.

Some gardeners grow their plants on single stems, others allow two stems to each plant. The vigor of each particular variety is the best guide. The strongest leaders are selected and the remainder cut away, and, as the growth proceeds, all the laterals, and for that matter, all the tendrils are pinched off. Tendrils are not needed with the cordon system; they have a bad habit of reaching over and taking a strangle hold on the head of a near shoot or flower stem. Some gardeners complain that it is not natural to grow sweet peas in this way; quite so, neither is it natural to grow sweet mums on one stem and on crown buds, or to trellis tomatoes, or to thin a bunch of grapes, but all are better for not being grown quite naturally. So it is with sweet peas. Apart from thinning and tying, all that is left to be done during the early stages is regular cultivation. If the plants make a good start, nothing else is required. If, for some unexplained reason, the plants do not make good headway, a light dose of nitrate of soda may be given, but keep off the stimulants unless it is necessary.

One thing I should mention regarding the removal of laterals, and that is, do not disbud too closely. Some va-

rieties have a mean habit of going blind when in a high state of cultivation, and if the laterals are all removed, there is an end of the plant. This often happens after a hot spell.

When the plants are well in flower, it is good to start feeding, the condition of the plants being the best guide. The first sign of smaller leaf or flower is the feeding sign. Liquid made from cow or sheep manure and applied in a weak state is very beneficial. I apply it by making a shallow trench six inches away from the plants and one along the center of the double row. This trench is filled with the solution and when it has disappeared, the earth is returned to its place. Once a week for an application is often enough at the beginning, but if the vines are growing fast, twice a week is permissible after the feeding has become regular. The diet may be changed to advantage, using some good standard fertilizer, such as Clay's, Mackereth's, etc. A good drink of superphosphate is always of benefit, but do not let your enthusiasm get the better of you in the way of feeding, especially if the vines are not over strong. Good strong, thrifty vines can stand a lot of feeding in favorable weather, providing the same is applied with common sense.

When the hot weather arrives, a mulch of coarse material is very beneficial. Decayed leaves or very old manure answers the purpose; at any rate, the mulch must be some medium that will not mat down and close the pores of the soil and cut off the air.

Every catalog describes the latest varieties of sweet peas as all producing four flowers to a stem, sometimes more. Sometimes they do; sometimes they don't. There are times when well-grown plants are full of four-flowered sprays, and often five and six, and there are other times when the same plants are full of three-flowered sprays and often two. The cause of this is that the plants have been overtaxed from bearing flowers or intense heat. An exhibitor who finds himself in the predicament of having only two or three flowers on a stem on the morning of the exhibition would be very fortunate if he gained a place in the first three. This condition can be overcome partly in normal weather by careful feeding, and partly by the method I shall now explain.

Some ten or fourteen days before we require a lot of good flowers, we remove from the vines all the flower stems that are more than an inch long. If the flower stems that appear next grow so rapidly that they will be over before the day of the show we also

remove these, the object being, of course, to have a new crop of fresh flowers just on time. In very warm weather a flower stem will advance from one inch long to full flower in five days. In cool weather they take twice as long. This is a trick that calls for good judgment founded on keen observation.

The worst enemies that we have to contend with are aphid and mildew. At Park Ridge the sparrows keep our vines quite free from the aphid, and we allow them to take a few flower buds in return for their service. If you must kill off the sparrows, then you must also kill off the aphid, or the aphid will kill the vines. A good nicotine preparation is the best aphid killer.

Mildew often follows a bad change in temperature, and at its first appearance, I get a quart of ammonia (22% strength) and one ounce of carbonate copper. When the copper is dissolved, we dilute nine gallons and spray thoroughly. This solution is also good for culinary peas.

Flowers for exhibition should be cut when they are dry. If it is necessary to cut while wet, shake the moisture off and arrange loosely in vases in a cool, airy room. The white, picotee and pale pinks are best if cut twenty-four hours before the time of showing, but the reds, purples and deep pinks are most fresh when cut on the morning of the show and stood a few hours in water. In arranging a stand, always avoid strong contrasts in colors, and place the taller flowers to the rear. A vase or two of the dark varieties in purple and maroon always add to the appearance of an exhibit, as these colors seem to add weight, especially if they are placed at the back corners.

Standing on the rustic bridge, in front of the waterfalls at the Great Exhibition of Ferns and Wild Flowers, held during May at Horticultural Hall, Boston, are (left to right) Mr. A. C. Burrage, Pres. Mass. Horticultural Society; Mrs. Richard Saltonstall, Mrs. Bayard Thayer and Prof. C. S. Sargent, of the Arnold Arboretum.

Hardy Perennials

By ARTHUR SMITH

IN a gardening book published about half a century ago it was stated that: "Deciduous shrubs are beyond all question the most important element in planting grounds, especially small ones."

At that period there were comparatively few species of flowering shrubs in use, and outside these, flower gardening was almost entirely confined to the bedding-out system, lawns being cut up into beds of all sizes and shapes, and gardening with hardy plants was practically unknown. While since then a great change for the better has generally taken place it is still possible to see those deplorable excrescences upon the landscape in the form of beds upon a lawn filled with tropical and sub-tropical rubbish for two or three months, and the rest of the year nothing but bare earth.

There is nothing artistic in a garden cut up into geometrical beds filled with bedding plants in which the natural beauties of the flowers are lowered to the level of being used in mere color design without any reference to the habits and idiosyncrasies of the plants themselves; clipping—especially in the case of carpet bedding—being always resorted to for the purpose of keeping the pattern geometrical. No true artist who is a lover of flowers and who is capable of seeing the beauty that exists in Nature would attempt to desecrate a garden or park with this tracery work which is degrading to the true art of landscape gardening. William Morris, in his *Hopes and Fears for Art*, wrote thus in connection with this style: "Another thing also much too commonly seen is an aberration of the human mind which otherwise I should have been ashamed to warn you. It is technically known as 'carpet-bedding.' Need I explain further? I blush with shame at the thought. This style of decoration seems to have been introduced and kept up as a manifestation of a gorgeous and highly elaborated style of gardening, a style which suggests the thought of enormous cost and labor to produce nothing but vulgar ostentation."

To the majority of people the great incentive in causing them to have a country home is to have a house surrounded by a garden and a place for rest and recuperation. But what is there restful to the eye or brain in a garden laid out in a stiff, formal manner, containing nothing but harsh glaring colors? What does a garden amount to which depends more or less entirely upon bedding plants? In the first place the lawn is spoiled by having beds cut into it; then it is unsafe to bed out before the end of May or early in June; July is well advanced before there is much effect and before September is finished frost generally does away with it all. So barely three months of flowers, where there are flowers at all, is the total which is obtained for the trouble and expense, and during the whole of that short period there is no more change in the appearance of the beds than in the patterns of the floor coverings of the house and they are both similarly interesting. The effects produced by carpet bedding and the bedding out system generally could be just as well obtained by artificial flowers, or by painting the colors upon wood and laying it upon the grass. If there is one thing more than another which has marred much of the ornamental surroundings of country homes it is this system with its comparatively enormous annual expenditure producing only ephemeral results and leaving the ground with nothing but beds of bare earth for the rest of the year.

But do the majority of people using the bedding out

system really prefer it? The present trend of ideas points somewhat to the contrary. The change in viewpoint has been long and slow in coming. For this there have been many reasons. In the past there have been too many gardeners who appear to have known of nothing but bedding plants wherewith to create a floral display, and in many sections today there is little or nothing else seen. The movement towards gardening with hardy plants has come more from owners than from professional gardeners. Estate owners have for years been complaining of the difficulty in obtaining men capable of planting and maintaining a garden of herbaceous perennials. Too many look upon greenhouse plants as the only ones worth much trouble and have been in the habit of despising hardy perennials, stigmatizing them as weeds.

Another reason why flower gardening with hardy perennials has been for so long conspicuous by its absence is due to the fact that so many landscape architects possess such a meager knowledge of them that they are apparently unable to grasp the many ways in which these subjects can be used. Plantings of trees and shrubs are arranged for by the acre, while at the same time herbaceous perennials are upon the smallest possible scale or are not provided for at all in their landscape plans.

In this connection, as well as in others, the object lessons seen in public parks are the reverse of what they should be. The introduction of politics into appointments for almost every public office is the more ridiculous when looked at from the point of view taken by a lover of natural beauty; ridiculousness which becomes a glaring farce when some appointments to the office of park superintendents are considered. Many of these political appointees look upon their position as a means of making as much money as possible before the other party comes into power; they have no sympathy or knowledge of their work and none of that love of it for its own sake which all true gardeners possess.

Public parks should be places where the people can see the best and highest embodiment of garden art, and the most advanced methods of plant culture. Unfortunately, however, it is too often the case that the only lessons to be learned is how not to do things.

In those instances where herbaceous perennials are used in public gardens the plantings are generally insignificant, upon too small a scale and entirely out of proportion with other things. The use of merely a dozen or so species of perennials in some out of the way corner when there are acres of trees, shrubs and huge beds of gaudy bedding plants is not calculated to cause people to realize the wide possibilities of gardening with hardy plants. Nature teaches differently by its masses of Asters, Golden Rod, etc., etc., which every one having the opportunity of seeing is delighted with. Why not create such-like features in city parks, and bring natural beauties into the heart of densely populated districts, the inhabitants of which rarely see the real country?

Of course dealing with these hardy perennials requires a much wider horticultural knowledge and experience than that necessary for handling ordinary ephemeral bedding plants.

The movement in the direction of using hardy plants and less glass which has been gradually increasing in intensity, has undoubtedly come to stay; for the reason that it is more economical when compared with results; more attractive the year through to all garden lovers and en-

thusiasts, and it affords greater space for greater variety.

This movement has during the past few years been greatly accelerated by the formation of Women's Garden Clubs, and there is every reason for believing that owners of gardens, large and small, are gradually becoming better educated in garden matters—which is what Garden Clubs presumably are for—and the more a person's education is extended along this line the more artistic and interesting will gardening with hardy plants appear.

The production of natural effects, refined by Art, should always be striven for in planning home surroundings. The characters of hardy perennials causes them to be the only plants suited to the natural style of flower gardening, however small or large a garden may be.

Species can be found adapted to every situation in which a plant of any kind will grow at all. Bare ground under trees where grass fails; a dry sunny bank; a swamp or bog; woodland walks; in fact any situation may be made permanently beautiful by them. The situation from which these plants are barred—and any others—is in beds cut in the lawn.

There is always a freshness in connection with perennials. A walk about a garden in which they have been planted invariably reveals something new, some flower which was not there a few days before; the monotonous feeling inseparable from bedding plants is out of the question, and during the whole year there is a never ending interest which tends to invigorate the brain and drive away *cumuli*.

The charm of association can exist in a garden of hardy flowers, and one can there form lasting friendships such as never can exist in a garden devoted to ephemeral bedding plants. If a hardy garden is given intelligent appreciation it will soon grow to have almost a human atmosphere. We meet old friends each year with added interest. How we watch for the blooming of some favorite! If it is late in appearing, how frequently we visit the spot day after day, until at last it arrives in all its fresh new-born beauty, but still the same old friend; not like the human friendships made upon a vacation tour to be forgotten before we reach home, but one which we can depend upon to visit and to cheer us with periodical faithfulness, and as "year after year the same dear things lift up the same fair faces," we would like to become perennial ourselves in order to the longer enjoy our hardy flower friends.

It must not be forgotten that *all* the charm and beauty of perennials, as well as with other permanent features of a garden, can not be obtained the first season after planting; patience must be exercised. The lack of patience may answer the question as to why the best features of the old-time gardens have been so lacking in America where there are so many homes without gardens in the real sense of the word. Lawns with a number of round, square, or other shaped beds dotted about them bedded out each Summer and open to the world in all their ugliness, are not gardens. As previously stated, the word garden means enclosed space, and it is the feeling of being shut in with Nature in all its beauty—grass, trees, flowers and sky—that causes the old-time garden to have its perennial charm. A garden should be nothing more—a real garden cannot be less—than an outdoor room of the house, sweet with memories, and associated with the hopes, fears and secrets of our lives.

Many of the old gardens were walled in, and the same idea is used in connection with the sunken garden, and provided it can be properly carried out is a garden feature worthy of more extended use.

A garden of this character can sometimes be made to form a special feature of country home surroundings.

It is not of course always the case that the existing conditions will permit this to be accomplished. Where it can be the following points—frequently ignored—are imperative. It should be so placed that one can step from the house or porch directly into it. It should be rectangular in outline and being walled in, it is practically part of the building. It must on no account form part of the general landscape, that is, the sunken garden must not be seen from any part of the place excepting from the side of the house on which it abuts. The excavated earth should be spread to a natural contour on the three sides and planted with shrubs and evergreens in harmony with, and in connection with, the general lay-out of the grounds. This planting will not only mask any portion of the wall appearing above the surface but will also act as a background to the inside picture. The beds inside should be rectangular, not, as is sometimes seen, radiating to a common center. Where the climate is suitable, the beds may be edged with dwarf Box, this should be kept to a height of about five inches. It goes without saying that hardy perennials are the only things admissible for planting the beds, as old-fashioned flowers are the only plants suitable for an old-fashioned garden.

In some cases where the outlines of these old-fashioned gardens have been reproduced, the gardens have been spoiled by being devoted to carpet bedding and to other such like ephemeral features. But where those enclosed flower gardens have been laid out upon a generous scale, properly set out with hardy plants, the effect is such that no one with the smallest amount of artistic perception would ever wish for the other method.

These walled-in gardens, being laid out upon rectangular lines, are by some termed formal; but the planting is absolutely informal, and it is only where the plants are rigidly arranged in formal designs that the term formal is strictly applicable. The straight lines of this garden are, however, so far unnatural, and it is this fact which renders it absolutely necessary that these special gardens should not form part of the landscape.

It is astonishing how many calling themselves landscape architects appear to be incapable of grasping this fundamental principle. Not long ago I saw two plans for new estates made by a landscape firm of some repute, in which what they termed formal gardens had been designed. In each case the garden was planned to be placed at some distance from the house, and was entirely open to the landscape. It is impossible to imagine anything more incongruous and wanting in good taste. Fortunately neither of the owners carried the plans out.

In connection with a garden of this kind a word about its walks appears necessary, because in such, one should be able to walk around it in the thinnest of shoes immediately after rain. In any case providing perfect drainage goes without saying, and from all points of view the hard red brick which is made for the purpose is the most satisfactory material to pave them with. Cement should never be considered for use in any garden walks. No doubt the most artistic walk is that paved with irregular shaped pieces of flag-stone with the interstices planted with dwarf subjects such as Thyme which emits its pleasant perfume when walked over, *Oxalis corniculata*, *Sedum acre*, and such like. Care must be taken to keep grass and other weeds from these walks, but if they entail somewhat more annual labor than those of brick, the additional old-world charm given to the garden will repay for the trouble.

The above old-fashioned garden has been alluded to because of late there has grown up a desire, on the part of those having room enough in their grounds, to possess one, and also because hardy perennials are the only plants suitable to use in it. But it must not be understood that

they cannot be planted elsewhere. On the contrary these plants lend themselves artistically to the general landscape scheme.

More often than not the use of shrubs is overdone, that is comparatively, as the quantity planted is too large in proportion to other things, and there is frequently thereby caused a general want of balance in country home surroundings as well as in public parks.

However good the selection of shrubs has been so as to obtain the longest possible flowering season from them, the majority bloom more or less early in the season, and the more northern the latitude the fewer late flowering ones there are which can be used. In any case a border of shrubs always presents a flowerless condition in some of its parts for a considerable period. Therefore the psychological position for herbaceous perennials is along the foreground of the shrubbery so as to illuminate the existence of a flowerless condition from any part during any period of the floral year: at the same time the shrubs afford the best possible background for the perennials. One would suppose that this idea would present itself to every one giving any thoughts to the subject, and especially to those who practice garden planning as a profession. It is, however, extremely rare to find this idea carried out in any landscape architect's plans.

For house decoration, no class of plants are so valuable for cut flowers as these. The artist in arranging flowers is glad when outdoor ones are available as they lack the stiffness and continual sameness of the stereotyped hot-house products.

Informal gardening with hardy plants is beyond dispute more economical in every way, especially when we take results into consideration. Not only is this the case as regards the actual amount of attention needed, but the annual cost of bedding-out plants and the work connected with them is saved. The sacrifice of the flower garden to plants which so far as the garden is concerned, perish every year, even superficially considered, appears an absurdity, without taking into account the hothouses; the propagation of plants by the thousand; the planting out at the busiest time of the year; the digging and storing in Autumn, and the care in Winter. Practically speaking there are nine months' care under glass for three months' effect out of doors in connection with bedding plants.

It would be better in every way if, so far as the flower garden is concerned, gardeners would see what can be done without the aid of the hot house. Some owners have reduced their glass with this end in view, and in one case within my own knowledge, the entire range of greenhouses was removed as the owner despaired of ever being able to get proper attention to gardening with hardy plants so long as the glass existed.

Before the advent of greenhouses our ancestors had their beautiful flower gardens, although the number of species they had to draw upon was small compared with the wealth of hardy flowers we have to our hands today, and there are still a large number of beautiful plants, native of this country, which are unknown in our gardens. For instance the native flora of our Rocky Mountain districts, especially the Western side, has been practically untouched. Therefore gardening with hardy plants presents unlimited possibilities without going to the trouble and expense of handling tropical species.

The recent Hardy Flower Show at Boston must have been an eye-opener to those who have hitherto looked with contempt upon, or who have been ignorant of the unsurpassed beauty of our native plants.

A further sign of the times is seen in the fact that many flower shows now give a prominent position to classes for hardy flowers, this is especially noteworthy in the case of a locality where up to recently nothing else

was thought of but the greenhouses which has this year placed hardy flowers in the premier position.

As a rule, a man who has been "bedding-out" all his life will make a lamentable failure in planting herbaceous perennials, and a thorough knowledge of their character is necessary before one can arrange a hardy border satisfactorily. The three most important things to know about one of these plants are, the height it will attain to, period and duration of blooming, and color of its flowers.

It is a great help to make a planting plan and have the arrangement of plants first put upon paper. By this means plants can be properly grouped and the color scheme made as artistically perfect as possible. Moreover, an opportunity is thus afforded to thoroughly think the matter out, and of knowing beforehand the actual number of plants of each species which will be required.

These plants should be set out in irregularly shaped groups; circles, squares, and rows should be avoided, so as to accomplish as far as possible the effects of Nature's planting. Although the taller species should generally be placed at the back of the border, yet the groups of these should run toward the front; at the same time the dwarf kinds should run toward the back to some extent between the groups of the taller ones. By these means a broken, wavy, and pleasing surface is obtained, and naturalness and informality secured. No method of arranging these plants can possibly be worse than that which is sometimes seen, of having a row of the tallest growing species along the back; then a row of those not quite so tall, and so on down to the dwarfest in front. One does not, of course, plant groups of dwarf species behind, and surrounded by groups of tall ones, but partially in front and partly between them. There is no harm, however, in finishing off a border, at its junction with the lawn, with an edging of quite dwarf subjects, such as *Phlox subulata*, *Sedum sieboldii*, and things of a similar character.

The number of species of herbaceous perennials is so large that it appears useless to attempt the mention of species. What to plant depends upon the conditions and one's individual taste, and gardens of hardy plants always reflect more or less the personality of the planter. The first aim should be to have a constant succession of flowers of varying forms and colors throughout the season appearing from all parts of the border. The fact that this is easily obtained is what constitutes one of the charms of gardening with hardy plants; every week, almost every day, gives a totally different impression from the days which have passed. Many of them will continue in flower for five months if not allowed to form seed, instances of the fact the more flowers which are cut the more flowers we have. Others give more than one distinct period of bloom; while others which only have one period of blooming leave a pleasing mass of foliage which rests the eye while passing from one group of flowers to another.

In connection with those kinds which only bloom once, it is possible to have two distinct species combined in one group so that it will give two distinct periods of flowers. As examples, Peonies flower rather early, and only once; if Lilies are planted among them they grow above the peony foliage and produce a beautiful effect. Another combination is that of Japan Iris and Hardy Chrysanthemums. The former flowering in June and July and the latter in the Autumn.

Another point to be considered is the size of the border and of the garden, as well as the distance of the border from the principal point of view. For instance as regards the latter, a large border with a background of shrubbery at the far side of an extensive lawn may have much bolder masses of color at a time in one place than a small border in a suburban lot. In the latter case one plant of

the scarlet Oriental Poppy would be as effective as a dozen in the other. Then in a small border plants of a strong; rampant growing nature like *Bocconia*, *Polygonum cuspidatum*, *Helianthus*, and such like, are better avoided as they would soon smother everything else near them.

The period during which a particular species is in flower and the duration of that period must be given due weight in making a selection and arrangement. Some will push their way through the snow in March, while others will bravely wave their blossoms after snow has fallen in November. Between these two extremes flowers can always be in evidence.

Bearing this in mind it is also obvious that a garden can be arranged so as to give its maximum effects at any special period; you can have a garden of Spring flowers; one devoted to species which are at their best at mid-Summer, or one containing nothing but Autumn flowering kinds. Thus, if a country house is only occupied for a month or two in the season, a selection may be made which will give the greatest possible quantity of flowers during those particular months; this is only possible, however, when the period of occupancy is the same every year. Recently, for instance, I was called in to design a hardy border for a client who did not occupy the house between the end of May until the middle of August, and who wanted as many flowers as possible during Spring and Autumn, and of course there was no trouble in giving effect to his desires.

The following extract from a news item which appeared in the *New York Sun and Herald* early this June speaks for itself:

"Vineland, N. J., May 27.—The Mothers' Garden of Remembrance here is bright with flowers for Memorial Day. So far as is known this is the only garden of its kind in America dedicated to the mothers of the soldiers and sailors in recognition of their patriotism and sacrifice. The Mothers' Garden is a little gem of the landscape gardener's art. Perennial flowers and evergreens, emblematic of the mother's everlasting love and remembrance grow within the garden. Extending from the central setting of the pool and bridge are wings of flower beds within which are planted those perennials so dear to the heart of the home loving mother. They are of many different varieties and always during the season some of them are in bloom."

ANNUAL MEETING OF AMERICAN ROSE SOCIETY

BECAUSE of the notable work done by Dr. E. M. Mills in organizing a string of Rose Societies across the State of New York, and because of the interest among amateurs in Central New York State, the Annual Meeting of The American Rose Society was this year held in Syracuse, N. Y.

The officers of the Syracuse Rose Society planned and carried out a series of events which resulted in a day which will long remain memorable to the officers of the National Society and others who were fortunate enough to enjoy this privilege.

The day began with the judging of the Syracuse Rose Show, staged in the Auditorium of the Y. M. C. A., and except that the number of exhibits were reduced after the ruinous rain storm of four days previous, this show reflected a standard mass creditable from the piewpoint of quality as well as quantity. Frederick L. Atkins of Rutherford, N. J., and John H. Dunlop of Richmond Hill, Ont., were the judges. The Park Department staged an extensive exhibit in the non-competitive class.

H. P. Dennison extended to the invited guests a cordial welcome, responded to, on behalf of the American Rose

Society, by President Pyle, Leonard Barron, editor of the *Garden Magazine*; John T. Roberts, Lawyer, Granger and Farmer; A. L. Shepard, Secretary of the Rochester Rose Society; F. L. Atkins, and Prof. E. A. White, each in turn regaled the guests with wit and wisdom rosewise at luncheon.

Another twenty miles run brought us to the magnificent home of Mr. and Mrs. Hiscock, the former presiding judge of the court of appeals of the State of New York. Here was found a rose garden of luxurious appointment, exquisite taste and excellent culture. Complete beds of twenty roses of a kind such as La Tosca, Willomere and others.

In this notable garden was held the business meeting with the usual reports showing the treasury in a more healthy condition than for many years past, and resulting in the re-election of the former officers whose terms had expired in 1922, Robert, Pyle, President; F. L. Atkins, Vice-President; John C. Wister, Secretary; Charles H. Totty, Treasurer for the ensuing year. The following Directors, whose terms expired in 1922, were re-elected for a term of three years: James Boyd, Dr. E. H. Mills, George H. Peterson.

The evening meeting was held in the Auditorium of the Y. M. C. A. and was attended by probably three hundred people and was in charge of the visiting rosarians with the floor of the Auditorium entirely devoted to the rose exhibits. The audience, after inspecting the roses, arranged themselves in the gallery and after the opening address by Dr. Mills, fifteen minute speeches were made by President Pyle, on The American Rose Society, Samuel E. Hillger, President of the Auburn Rose Society, on the Building of a Local Rose Society; Mr. F. L. Atkins, on the Use of Roses in Public places; Mr. Fred C. Wallace, of Canandaigua, N. Y., on Help for the Amateur; and Mr. J. Horace McFarland on Climbing Roses and Climbing Memberships, in which he clearly pointed out that the success of a Rose Society either local or national depends absolutely upon the activities of the members themselves.

In Auburn on June 16th, 1922, we were met by Mr. Hillger, President of the Auburn Rose Society and Mr. Adams, Secretary, and by Mr. David M. Dunning, patron of the rose, long an eminent rose grower of Auburn.

The officers of the American Rose Society were taken on a tour of Auburn beginning with the famous Prison in which have been developed separate rose gardens for the men and for the women, not to mention the greenhouses. Then to the gardens of the Auburn Theological Seminary, Dr. Stewart presiding.

We visited also the gardens surrounding the residence of the famous General MacDougal, George Pierson and Mrs. C. W. Ross. This series of visits found their culmination in the garden of David M. Dunning, whose success in growing outdoor roses has for many years made his home a Mecca for rose lovers. A specimen of Frau Karl Druschki in veritable billows of bloom with wrist sized trunk of ten feet high was only one of the outstanding varieties which included among others most prominently, Mrs. Weymyss Quinn, Glorie Chedane Guinoisseau, Maman Turbat, Lady Pirrie, Gustav Grunerwald, G. Amade Hammond, Avoca, a plant in full bloom six feet high. Cissie Easlea, one of the richest yellows, though not quite such a favorite with Mr. Dunning as is Daily Mail.

Mr. Ferrin was the next one to welcome to his home some 75 guests who came, saw and were filled with delight upon seeing the display in full bloom of some three hundred rose plants including not only climbers, the best of which was Paul's Scarlet Climber, Polyanthas, among

(Continued on page 214)

That Botanical Chap Calls Again

FLORUM AMATOR

“WELL, almost a year has passed since I was in your office. I called last year in August and I saw the editor then. We had a delightful time with each other and studied botany together. I brought plant specimens with me and played the part of teacher and he of pupil. He at first argued with us a little about taking his part, but proved a good pupil after he warmed up under instructions, and, I presume, has remembered his lesson; is he in today?”

We looked up rather reluctantly from the work before us on our desk, as we heard these words uttered at our elbow, and recognized at once “That Botanical Chap” who called on us last year. He had a large box under his arm, and we knew what was in store for us. “The editor is not in today,” we answered. “What can we do for you?” “Perhaps you are the assistant editress,” he said. “We are one of his assistants,” we replied. “Good,” said he, “you may be the chief editress some day; women are making such rapid advances in many occupations and professions.”

As he diplomatically uttered this bit of flattery, he drew a chair up near our desk in response to our invitation to him to take a seat, and, placing the big box across his knees, began deliberately to untie the string which held the paper wrapping on the box, saying, as he proceeded with his work: “I have some specimens of plants here which I am going to show you. You have no doubt some knowledge of botany, the most interesting of all the natural sciences, and nearest home; not away off like astronomy. I had to gather these specimens in the rain; no balmy June this year; it has rained almost every day; Perhaps July will be sunny.”

He took out of his box a plant. “This,” said he, “is an ideal specimen; it has the roots, stem, leaves, flowers, and seed pods, and you are able to observe every part of the plant. You cannot always have a complete plant like this, but for botanical purposes you should always obtain as nearly an entire plant as possible; if that is not feasible on account of its large size, then gather portions representing the different parts of the plant, for example both radical and stem leaves, a section of the stem of sufficient length to show the manner of growth, another section to show the mode of inflorescence, flowers, seeds, and root. When you cannot obtain all of these, gather as many as you can. In the case of trees and shrubs, representative branches having leaves, flowers, and if possible fruit or seed pods will have to suffice. I hope you will never do such a stupid thing as many people do, namely, send a botanist a leaf or two or a single flower of a plant, and request him to give you its name. He may even from such a scanty data be able to identify the plant if he is familiar with it, but if not, he stands a small chance of learning its name through a systematic botanical analysis.

You say that you have not a working knowledge of systematic botany sufficient to enable you to analyze a flower unknown to you and so learn its name. It would be a valuable acquisition, but never mind, recall what you can of what you learned of botany in school or college, none too much, probably, and make use of it, and we will, no doubt, get along well looking these plants over together, and you will enjoy the hour's study.” We almost jumped from our chairs as he said the word “hour,” but he continued not to notice it, and we became resigned to a long wait in the end proved a profitable and pleasurable lesson. “That Botanical Chap.”

“We will not,” said he, “attempt a strict analysis of these specimens I have brought with me, though that would be a profitable way to spend our time if we had a botanical microscope, and needles and a sharp knife and a strong natural light at our command, but we will observe some of the pronounced features of each and note the derivation of both the generic and specific name, and learn what uses the plant has, if any, and so weave a little story, as it were, about the plant, which will enable you to recall its name whenever you see it, for you, of course, know it is far easier to remember and recall a name when it is associated with other names or facts.

“This specimen, as I said before, is an ideal one, because it represents every part of this rather pretty, native yellow-flowered plant. This is *Lysimachia quadrifolia*, whose common name is Loosestrife. It was named in honor of Lysimachus, a general of Alexander the Great, and later King of Thrace. The name is composed of two Greek words, *lisis*, a loosing from, *machia*, strife. Its specific name is *quadrifolia*; Latin, *quadri*, four, and *folia*, leaves, because its leaves are arranged on its stem for the most part in whorls of four. Now look at this plant and as you look, fix in your memory whom it was named after and what the name is derived from and what each part means, and what the specific name was derived from and what it means, and you will always be able on sight to recall the name of this plant.

“This white-flowered plant, which I also pulled up entire, is also a complete specimen. The name of this plant is *Achillea millefolium*. Its common name is Yarrow or Milfoil. It was named in honor of Achilles the Greek, who fought in the Trojan War in 1184 B. C., and whom the Greek poet, Homer, immortalized in his Iliad. Achilles is said to have been the first to discover the medicinal virtues of this plant. The specific name, *millefolium*, is from the Latin *mille*, thousand, and *folium*, a leaf, the leaves of this plant being so finely dissected as to make the divisions appear almost innumerable. This gives it one of its common names, Milfoil; the other Yarrow is of doubtful derivation but is perhaps from the old English, *Yare*, meaning prompt, effective, perhaps referring to the medicinal virtue which Achilles discovered. Now smell of this plant and note and remember that it is strong-scented and put with it the fact that its leaves sometimes have been used for smoking. See, you and I have woven another little story around *Achillea millefolium*, which will enable us to always recall its name when we see it. Why, it is just as easy to remember the name of this plant, which we have examined, as to remember the name San Francisco, which you, perhaps, have never seen, is it not?

“This is a marsh, or sometimes aquatic plant. Aquatic plants, as you probably know, grow in the water; the name aquatic is derived from the Latin *aqua*, water. A knowledge of Latin and Greek is a great help to anyone studying the natural sciences. Note that the leaves of this plant are the shape of an Indian arrow-head. This fact gives this plant its generic botanical name, *Sagittaria*, derived from the Latin *Sagitta*, an arrow, and also its common name, Arrow-Head. Now, there is another specimen of this same plant, and here is a third. Though the leaves are of the same general arrow-head form, those of specimen number one are broad and obtuse, those of number two broad and acute, and of number three narrow. This gives this plant its specific name *variabilis*, which is

a Latin word and means, variable. The varietal name of one is *obtus*, a Latin word meaning, obtuse; of two, *latifolia*, Latin word meaning broad-leaved; of three *angustifolia*, a Latin word meaning narrow-leaved. Now hereafter when in your country walks you see this plant you certainly will easily recall its name, as you note the form of its leaves, and how plants near each other vary in foliage, and say this is *Sagittaria variabilis*.

"This plant is a true aquatic, but always grows in shallow water. I had to wade to gather this specimen and I had to reach down to the bottom to obtain this piece of creeping rootstock from which the heart-shaped leaves and the one-leaved stem of this plant spring. This is the only specimen we have with us which grows up from a subterranean stem, which is called a rhizome, or rootstock. Note how roots put forth from the nodes of this rhizome, but the leaves and flower stem from its apex. Other commonly seen plants which spring up from rootstocks are *Acorus calamus*, Sweet Flag, and *Iris versicolor*, Flower-De-Luce. The violet-blue flowers of this plant have wilted already; that is because they are ephemeral, that is last only for a day, Greek again, *epi* for, *hemera* a day. Not a few plants have been named in honor of some scientist, usually a botanist. The general name of this is *Pontederia*, named after Ponteder, a professor at Padua in the beginning of the last century, and its specific name is *cordata*, from the Latin, *cor*, heart, so called on account of its leaves, some of which you note are heart-shaped. Its common name is Pickerel-Weed, so called because that fish in hot summer days likes to lie under the shade of its leaves. When next you visit the shallow-watered cove of some pond or river look for this rather pretty aquatic, *Pontederia cordata*, the upper lobe of whose violet-blue perianth is marked with two yellow spots, a feature which you will easily note in the fresh flower."

At this point "That Botanical Chap" suddenly looked at his watch and immediately began to repack his specimens, saying as he so did: "Next time I call I will bring along with me some specimens, my botany, a botanical microscope et cetera, and we will analyze together some plants unknown to you and in this way learn their names."

THE TRAINING OF GARDENERS

THE Massachusetts Agricultural College takes pleasure in announcing a co-operative arrangement with the National Association of Gardeners whereby a special course of training for gardeners is to be established. Tentative plans for this course are set forth below, and it is expected that the first pupils under this arrangement will be admitted to Massachusetts Agricultural College with the opening of the Fall term Sept. 27, 1922.

PURPOSE

The traditional training of gardeners in Europe has been conducted through a well-established apprentice system. This training requires several years of practical work in various branches of the art. The American system, by contrast, has developed extended courses in school and college giving scientific and theoretical training, with a minimum of practical experience. In the present plan the attempt is made to combine these two systems with the hope of securing the benefits of both. The Massachusetts Agricultural College will conduct the theoretical instruction, while the National Association of Gardeners will take the responsibility of directing a prescribed apprenticeship. These two lines of work will be carefully coordinated and pupils will be held to a strict accountability in both.

This course of training is planned with the expectation

of fitting men for practical gardening, either as commercial gardeners, florists or nurserymen conducting productive business enterprises of their own, or as gardeners on estates, foremen and superintendents in parks or cemeteries, or as gardeners, florists or nurserymen in the employ of commercial establishments.

PLAN

The general plan of instruction is based upon the two-year course already in successful operation at Massachusetts Agricultural College. Students fitted to take the course will be admitted each year in September, and will remain in residence at the College for six months. During this time they will pursue general studies in fruit growing, flower growing, vegetable growing, forestry, general horticulture and such elementary subjects as may be necessary. These classes will close the last week in March and students will be sent to various commercial establishments and private estates for a Summer of practical work. Every effort will be made to see that pupils are advantageously placed so as to secure the best possible experience; and this Summer's apprenticeship will be supervised by a committee representing jointly the Massachusetts Agricultural College and the National Association of Gardeners.

At the end of the Summer students will return to the College for an additional period of nine months' study. They will thus complete this part of the course in the following June, and if successful will receive a certificate from the College. From this point they will enter upon an apprenticeship of two years, to be arranged and supervised by the National Association of Gardeners. At the end of this time they will be examined by a special board and if successful will receive the diploma of the National Association of Gardeners.

ADMISSION

Students must be 17 years of age or over at the time of admission and must have completed an elementary school course or its equivalent, and must be able to use the English language with reasonable facility. Under the plan proposed special consideration will be given to pupils coming upon the recommendation of the National Association of Gardeners.

EXPENSES

Tuition at the Massachusetts Agricultural College is free to citizens of the state. Pupils from outside the state are charged \$60 a term. This will make the tuition charge for the first year \$120 and for the second year \$180. There are small laboratory fees charged in certain courses and other fees for incidentals, but these will not average above \$10 a term. Board and room in Amherst cost from \$8 to \$12 a week.

INFORMATION

This work will all be under the co-operative management of the Massachusetts Agricultural College and the National Association of Gardeners. This association is represented for the present by the following members of its Executive Committee: Mr. Robert Cameron, Ipswich, Mass.; Mr. William N. Craig, Brookline, Mass., and Mr. M. C. Ebel, New York. The immediate direction of instruction will be in the hands of Professor Frank A. Waugh, Amherst, Mass., to whom may be addressed all correspondence regarding these matters.

"Whatever the weather may be," says he,
 "Whatever the weather may be,
 It's the song ye sing, and the smiles ye wear,
 That's a-makin' the sun shine everywhere."

JAMES WHITCOMB RILEY

Some Worth While Climbers

BERTHA BERBERT HAMMOND

THE magic touch of a fairy wand could scarcely do more to transform a commonplace building, porch or other object than the graceful festoons of a luxuriant, well chosen vine. Nature is prodigal in her use of vines and drapes them around trees and shrubs and over stones and fences in a wonderfully effective manner, making beauty spots of places that would otherwise mar the landscape. Well may we copy this peculiarity in Nature and by making free use of vines add to the beauty and comfort of our surroundings in a natural and simple manner. There is something very inviting and cozy on a porch that is screened, shaded and cooled by some ornamental climber and the humblest of dwellings appears charming and home-like when beautified by an attractive vine.

There are a large number of handsome vines, some are suitable for the purpose of growing on buildings and others are at their best when grown on lower structures such as trellis, pergola or fence. Some are hardy and others are easily grown from seed to maturity in one season. With such a wide range of choice, care should be exercised in selecting vines that will prove the most satisfactory in the location and for the purpose that they are desired.

The Boston or Japan ivy (*Ampelopsis veitchii*) a hardy, rapid grower which clings to stone, brick and wood with a tenacious hold, is one of the best of climbers, and in the Autumn its foliage, with its rich crimson and orange coloring is unsurpassed in gorgeousness. The well-known Virginia creeper (*Ampelopsis quinquefolia*) sometimes called American Ivy, also assumes a vivid autumnal coloring that is very decorative. This beautiful native vine without any special care, will in a comparatively short time beautify any object over which it may climb. The sweet scented honeysuckles are especially esteemed for use on a porch where their delicious fragrance may be fully enjoyed. They grow and bloom freely and are quite lasting and ornamental. Hall's honeysuckle (*Halliana*), a Japanese variety, is evergreen in its nature, the leaves retaining their color long after heavy frosts.

In the Spring when our Wistaria is covered with its graceful drooping clusters of lavender tinted blooms, this vine seems the most beautiful and desirable of hardy climbers, even though on account of its tendency to pry under shingles we thought it wise to train it from porch to tree instead of allowing it to climb over the roof at its own sweet will. The different varieties of clematis are attractive and popular. They are hardy, rapid in growth and profuse in bloom. *Clematis Jackmani* which bears in great profusion large flowers of a royal purple color is the most showy of its kind and the smaller-flowered *Clematis paniculata* which in the early fall becomes literally covered with a mass of white, fragrant, star-like blossoms, has won recognition as a most desirable climber. The fact that its silky seed vessels are highly ornamental, adds to its popularity. *Clematis Virginiana*, a native variety, with somewhat coarser foliage and flowers than *Clematis paniculata* is loved alike for its hardiness and wild beauty and is tenderly known in many localities as "Traveler's Joy." Sir Walter Scott alludes to the clematis as

That favored flower

That bears the name of Virgin's Bower.

Dutchman's Pipe (*Aristolochia siphon*) which attains a height of twenty to thirty feet is valuable for training

on the veranda or against the side of the house. Its broad tropical-looking leaves and odd pipe-shaped, brownish-yellow flowers make it a floral curiosity. The trumpet vine (*Bignonia*) with its brilliant flowers deserves honorable mention as one of the desirable ornamental climbers that is valuable for the covering of walls or houses.

Among the roses there are a number of charming hardy climbers that are so especially meritorious that a choice is often difficult. The crimson Rambler has probably been the most widely cultivated and may be found climbing on thousands of houses and arbors. It is a very hardy variety and though its season of bloom is none too long, it makes a brilliant display while its numerous clusters of bright flowers last. Of late its popularity has waned somewhat due to newer, finer introductions and to the return to favor of some of the old-fashioned sorts dear to the heart for sentimental reasons usually, as the modern climbing roses are for the most part superior. Take for instance the "Tausendschön" which lives up to the translation of its name "Thousand Beauties" in that it bears a multitude of clustered bouquets of attractive flowers. The pink climber Dorothy Perkins is a free-blooming, fragrant rose with lasting qualities, and Silver Moon with its large nearly double flowers with silvery white petals is a rose of considerable distinction. The double-flowered rose Source d'or is a good climber of a pleasing yellow color.

Annual vines will fulfill their mission to the utmost where a quick covering of foliage is desired, but in order to avoid keen regrets and endless grubbing it is wise to keep at a distance such persistent spreaders as the wild cucumber, common morning glory and the widely advertised Japanese Kudzu that is the modern rival of the magic vine in "Jack and the Bean Stalk." These vines certainly grow with incredible rapidity but they continue to spread and grow long after the temporary need of a vine covering is past and become a real pest to the hapless gardener.

The annual hop (*Humulus*) introduced from Japan is a rapid climber attaining in almost a month's time a height of twenty feet or more and covering veranda or arbor with a dense shade-giving foliage that seems drought and insect proof. There are a number of varieties of *Ipomoea* that are especially delicate and beautiful, the Cypress Vine (*Ipomoea quamoclit*) a semi-hardy sort with dainty ferny foliage and handsome flowers, being probably the most used.

Competent Gardeners

The comforts and products of a country home are increased by employing a competent gardener; if you want to engage one, write us.

Please give particulars regarding place and say whether married or single man is wanted. We have been supplying them for years to the best people everywhere. No fee asked.

The Greenhouse, Month to Month

GEORGE F. STEWART

THE last half of July and the first part of August keep the greenhouse man on the move continually. Plants that are getting well rooted require a great amount of water and moisture to counteract the strong sunshine. Keep all the paths and under the benches well damped until far in the afternoon on all bright days. Keep all plants that are likely to burn shaded until well towards the end of September.

Watch a chance for any wet or cloudy days for fumigating as greenfly breeds fast in the hot weather. Do not wait until it is seen on the plants—use prevention rather than cure. Mealy bug and scale will need to be continually hunted for, as, when they get a hold, they are not easily driven off. Dust under the benches every now and then with air-slaked lime which helps to keep the atmosphere sweet and destroys any snails that may be about.

Any repairs that need to be made in the greenhouse should now be attended to, as many plants may be placed out doors which will allow more room to move around. See also that the heating plants and pipes are in good shape as it is no joke to have a breakdown on a frosty night in Winter.

Chrysanthemums will be well rooted in their flowering pots and must be generously fed to keep up the strength of the wood and to give a healthy color to the foliage. Syringe the leaves occasionally with soft coal soot water which lends a nice glossy appearance to the foliage, and insects prefer not to be near it. Side growths will now begin to be troublesome and should be removed as soon as they can be taken hold of. The bush plants should be held in shape by pinching up to the first of August. Some of the varieties will come blind if stopped after that date. See that they are well supported by a few stakes set around them to which is tied a piece of string, as they are easily broken down when being syringed. I find it a good plan to put in a batch of cuttings about August first of such varieties as E. D. Godfrey, Giza, Miss Isabelle, Jane Inglis, Mrs. Buckingham, November Glow, Margaret Waite, William Lincoln. After they are rooted we put a dozen cuttings into an eight-inch pan in a fairly rich sandy loam and set them on a shelf near the glass. By Christmas they have become nice plants, about a foot high, and come in very useful for decorative work at that season. No doubt there are other varieties which would answer for that purpose but these mentioned we find most reliable; they set bud. Several others we have tried but they come blind struck at that date and, of course, are useless.

Hard wood plants will be plunged outdoors. Syringe them regularly and stimulate with Clay's fertilizer and soot water, also a little weak cow manure water until they set bud. An application once a week alternately will be sufficient to keep the foliage in good color, and will also build up strong wood.

Look well after the cyclamen plants and shift them along before they get pot bound. Use a good fibrous loam with some nice flaky oak leaves, adding a third of dried cow manure, also a little lime, and, of course, sand and charcoal to keep the compost porous. Very few in this country bother with left-over cyclamen plants nowadays, but the largest plant we have ever seen was a two-year-old plant. They are better if not dried off. A firm

crown should be selected if they are to be grown the second year. Corms that have a scattered appearance should be discarded. Secure cyclamen seeds in August for next year, being sure to get fresh seeds as old seeds take a long time to germinate. We sowed in August one year and they did not come up until the following February. Space the seeds equally in a good leafy loam and let them remain in the seed box until they have a nice little tuft of leaves.

Seeds of such annuals as are wanted for next Winter flowering are better if sown early in August. *Calendula*, *dimorphotheca*, *lupine Hartwegii*, stocks, etc., are all very useful for cutting in Winter.

Those who want nice specimens of fuchsias for next Summer should put in their cuttings about the last week in July. Select nice soft points of the shoots, about two inches long, and put them in sand. Space them well and water every bright day until they show signs of rooting. Arabella Improved, Gracilis, Monarch, Rollinsoniana, Rose of Castile, Speciosa, William Bond, all make good plants if properly trained by pinching.

Those who wish freesias for Christmas better get them potted by the last of July. We use bulbs that have been on the place many years and find that they force early, much better than those one can buy. They start away more evenly in the pots. We use ten bulbs to a five-inch pot and leave them outdoors until there is danger of frost.

Plants that flower at this time of the year are always acceptable. The Kalanchoes were once well-known but now they are never seen, although they certainly deserve a place in the greenhouse. Their culture is the same as Kalosanthus. *Kalanchoe flammea* is a good variety as is also *carnea* and *kevensis*. Many of these old plants ought to be revived. *Chironia linoides* is another useful plant at this season. *Stephanotis floribunda* is just coming into flower; it makes a handsome specimen when trained on a trellis.

The Allamandas are also beginning to flower, and who could wish a better bush plant than *Allamanda Williamsii* when in flower? Later on Lapagerias will bloom. Some of us can remember seeing trained pot plants of them with three hundred open flowers.

Ixora Fraseri is flowering with us now. It is one of the best of the ixoras. As the *achimenes* pass out of bloom, put them outside in a frame and gradually let them ripen off. These remarks apply also to gloxinias and caladiums. In the Fall remove them to warmer quarters. Many of the bulbous plants die from too cold treatment while they are resting.

In August shake out the Lachenalias and put them in fresh soil. Loam, leaf mold and about a third of dried cow manure is a good compost to pot them in. Twelve bulbs to an eight-inch pan makes a nice plant, but pots as small as three inches with a few bulbs in them, are very attractive plants for Winter use. Allow them to stay outdoors until there is danger of frost.

If possible, bulbs for early forcing should be secured in August. Paper Whites and Roman hyacinths, if they are desired early, should be well rooted by the time frost comes. In tulips, *Duc Van Thol* is forced for very early.

Tropical plants such as crotons, marantas, anthuriums, etc., are now growing freely and should have plenty of

space for developing their foliage. Top dressings with dustings of Clay's fertilizer and soft coal soot alternately will give rich color to the foliage and stimulate growth. See that they are shaded from the sun. Crotons, however, will take a very light shade.

Adiantum ferns should be gone over and all weak fronds removed to admit a free circulation of air through the foliage. Keep a sharp lookout for slugs as in no time they will ruin a plant. Dust between the pots with air-slaked lime occasionally, and this will take care of them. Sprinkle the top of the soil with soft coal soot which will take care of any that may have gone into the pot.

Have a good batch of Boston ferns for Fall and Winter use, also some of the better sports. The best way to keep up stock of them is to plant a few out on a bench in a light leafy soil. Many of the other ferns such as Davallias are very decorative. *D. fijiensis* and *Mooreana* make noble specimens. The elegant little variety *Tyermannii* is also worth a place in any collection. Gleichenias make handsome specimens and also Cibotiums and polypodiums. These plants all grow well in compost of good fibrous loam and flaky leaves with sand enough to keep porous.

Keep propagating poinsettia cuttings up to the end of August in dwarf pans for Christmas. Dipladenias are now flowering freely and to keep them in good condition will take stimulating with manure water. We find that cow manure, Clay's fertilizer and soft coal soot alternately once a week agrees well with them. Pinch the shoots immediately ahead of the flower stems. We find that by so doing, it will make any shoot that seems to be standing still start away and catch up to flowering along with the others. The vigor is apt to run to the shoots near the top of the plant unless they are pinched.

Keep plenty of moisture around the benches and floors where the orchids are grown and look out for slugs. Insect pests must also be hunted for all the time. Thrips are liable to get a foothold on miltonias and odontoglossums unless they are dipped or sponged occasionally. Keep plenty of moisture at the roots of the cattleyas until they have finished their growths. Dendrobiums are also growing freely. They need only a very light shade and must also have plenty of water and stimulating with weak hen manure water. Give calanthes plenty of heat and water until the new bulb is finished, and feed them freely. Always keep a crack of air on, as I think it prevents leaf spot. Grape thinning should be finished, and the work will now be largely routine, pinching laterals and attending to watering and airing. Stop syringing as soon as signs of coloring are detected; also see that they have enough water to carry them over the ripening period, as too much water is liable to give cracked berries.

Melons may still be planted for a succession crop where room is available.

Pot fruit that has fruited can now be repotted. Try and get them into the same size of pot or tub if possible. The roots may be reduced by loosening around the ball and any of the strong ones cut back. Use a good strong loam and pot firmly. Syringe frequently to keep the shoots from flagging. The object is to get good root action before the leaves fall.

Runners of strawberries should be secured as early as possible by those who intend to force them during the Winter. Pot them in 2½-inch pots as soon as good strong crowns can be secured with a few roots on them. Keep them fairly close in a frame until they get established. A light shade will be necessary to prevent wilting. Gradually give more air as they establish themselves. In two weeks they ought to be fit to pot along into 3½-inch pots, and then as quickly as possible into 4½-inch pots. Marshall, Wm. Belt and Nick Ochner are excellent forcing varieties.

The best advice for the hot months is look out for watering and shading and insect pests and stimulate plants that are root bound until they show signs of flowering.

SPECIMEN POINSETTIAS

John S. Doig

THE illustration is of two specimen poinsettias which are six feet, nine inches in height. The heads measure seventeen inches across from tip to tip of bracts. These plants were grown on from last year, 1920 stock, and were started up in the usual manner; first shaken out of the old soil and repotted in five-inch pots with a

Two specimen poinsettias.

mixture of good fibrous loam, cow manure, and bone meal. After having become well rooted in the five-inch pots, they were then repotted into seven-inch pots, from which they developed into the specimens as pictured. They kept their foliage well, five of them making a handsome showing when cut and placed in a large vase, with *Euphorbia Jacquiniaeflora* which kept in good shape for ten days in a room with a temperature ranging from sixty-five to seventy-five degrees. The plants held their shape very well in the same room for three weeks, after which they were cut and used as cut flowers.

A PRACTICAL HANDBOOK OF Trees, Shrubs, Vines and Herbaceous Perennials

By JOHN KIRKEGAARD

Formerly Assistant to Director of the Royal Botanical Gardens, Copenhagen, Denmark. Latterly Twenty Years in American Forestry and Botanical Work.

Illustrations in Sepia. Planting Plans. 410 pages. 8vo. Beautifully bound in cloth. Price \$2.50 net. Mailing price \$2.71.

The character of information may be summed up in the subtitle of the book: THE HARDY AND ORNAMENTAL VARIETIES, THEIR CHARACTERISTICS, Uses and PROPAGATION.

Work for the Month in the Garden

SAMUEL GOLDING

THE recent and often too abundant rains have had in many cases a somewhat discouraging effect on the vegetable grower, especially so where the planter has a heavy and retentive soil to contend with. On light and sandy soils, the growth of many subjects is most rampant and it has been a continuous struggle to keep the weeds in check. The frequent rains make effective cultivation a matter of some difficulty and the soft growth makes for fungoid diseases.

However, the remarkable growth of trees and shrubs and the thrifty appearance of most subjects in the flower garden and borders augers well for fine displays in the Fall, to say nothing of what we may expect next Spring, providing that the wood will be well ripened before Winter comes. The lawns are most verdant and restful to the eye, looking like early Spring instead of July, but at this time the Summer grass is oftentimes much in evidence and must be combatted with rake and mowing machine.

Reports of the pea crop in this locality have been generally unfavorable for this season, the climatic conditions being adverse to fine growth during May and early June when peas usually make their best growth, and very light crops are the result. The short supply of this most important and popular vegetable has made the perfect supply and succession of vegetables difficult to maintain. However, a bounteous Providence provides that the condition which may be unfavorable to some subjects is that which others revel in. String beans came in early with bumper crops.

When the peas have been removed, there is good space for celery, new strawberry plantations, late sweet corn or late cabbage. If celery is grown, some rapid maturing small crop can be planted between the rows, such as beets, horn carrots, lettuce, etc.

Make the last planting of corn about the middle of July (that of course means where the latitude is similar to that of New York) using any of the popular early varieties. Golden Bantam is very good for this purpose. Remove all basal growth from the growing corn and keep them well cultivated between the rows.

Plant out late celery and keep it well supplied with water. Spray the early plants with Bordeaux Mixture to prevent, or check rust. Continue to sow string beans and other small crops; also lettuce for Fall use. Tie up endive when large enough.

Continue to spray late potatoes for bugs and blights. The early varieties of potatoes will be fit to use now. Take up enough at one time for daily use as they will continue to grow until ripe.

Plant out new strawberry beds as soon as well rooted runners are available and can be lifted with a nice ball of earth. It is good practice to layer them into pots so that they can be removed as soon as they are well rooted, and the old plants removed to make space for cauliflower or cabbage. The pot grown strawberries are easier to handle in the event that the land for the new plantation is not at once available. Before planting make the ground firm; do not plant too deep, and give the young plants every encouragement to help them form fine crowns by the Fall. Keep off all surplus runners from the old plants that are retained for another season and fork in a dressing of bonemeal.

Keep an eye on asparagus as at this season it often times suffers from the attack of the larvæ of the asparagus beetle, and spray with Arsenate of Lead, or dust over when the dew is on in the morning.

Keep the tomato vines thinned to admit light and air to the fruits. A most satisfactory way is to grow them upon racks or trellises as they are easier to handle.

A dressing of some approved fertilizer will be of great benefit to most of the growing crops at this time, even though a liberal supply of manure was dug in in the Spring, for where intensive cultivation is carried out, the soil becomes somewhat exhausted after one crop and it is therefore good practice to add some plant food from time to time if we would get the best out of the land.

During wet periods it is advisable to raise the fruit of melons off the ground, pieces of wood, tile, slate or small inverted pots answering the purpose.

Spray the currant and gooseberry bushes as soon as they are cleared of fruit to keep the foliage free from pests. The work among fruit trees, known as Summer pruning can now be done. This is necessary where trained and dwarf trees are grown. The growths should be pinched back to about five leaves (except the leaders), but this is like most other gardening operations, no hard and fast rule can be made, and so some judgment must be exercised. Where the growths are extra vigorous and fruitless the tree should be root-pruned in the Fall. This will check excessive wood growth and makes for the formation of fruit buds. When apples or pears are thick and fine specimens are wanted, they should be thinned early. This attention well repays the time spent.

At this time the work in the flower garden consists of staking and tying, and keeping the insect pests away. Keep dahlias securely tied as they are easily broken or damaged during storms, and spray with Aphine to ward off attacks of aphid and other insect pests.

Transplant the seedlings of biennials and allow them plenty of room to develop into sturdy plants by the Fall. Take the cuttings of any stock propagated last month out of the sand when well rooted and plant out in well prepared ground.

Sow the seed of pansies, double daisies and myosotis for next Spring bedding. Some of the early blooming annuals may yet be sown for late cut flowers. Pick off all seed pods from continuous blooming plants as they cannot be expected to carry a crop of seed and then bloom again later. Pyrethrums, gaillardias, and *salvia pratensis* are the type of plants alluded to.

Cut out much of the old wood from rambler roses and tie up the new growths, allowing them plenty of room to grow and to get well ripened if we are to expect a fine show of bloom next year. Watch for the appearance of mildew and take early measures to combat it.

Give the teas and hybrids a good dressing of fertilizer as this will encourage strong growth for Fall blooming; keep the beds free from weeds by frequent cultivation and spray with Fungine for mildew.

Watch the evergreens, rhododendrons and azalea plantations for red spider which is their most persistent enemy, especially during hot dry spells. Wilson's O. K. Spray is effective in dealing with it.

BUDDING AND LAYERING ROSES

ROSE budding used to be an important item in the routine of a gardener's life and work. Then, as now, the most successful practitioner had no fixed and definite dates for his various operations. He left rigid calendrical gardening to others, for he realized full well that weather plays an important part in gardening. Successes and failures, particularly the latter, soon teach that it is the season and weather and not the calendar that must be studied if the best results are to attend our efforts. The time for outdoor rose budding is when the sap runs freely, so that the bark may be easily separated from the stem, and when the selected bud may be cleanly detached in its entirety. These two must coincide. It does not matter how beautifully clean the bark may be lifted on the stock if a perfect bud may not be taken to fit on it. Then the weather immediately following the budding has to be considered. Should it be unusually hot and dry, the bud is more than likely to shrivel before a union can be formed with the stock. On the other hand, cold and wet weather is equally fatal in that under these conditions the bud lies in danger of decomposition. So, as in most affairs, it is the happy mean in the weather that is needed for successful budding. These combinations of circumstances are generally found during July.

As to which method of budding is favored, it does not seem to matter whether it is the T-shaped incision, the inverted T, the square shield or the circular so long as, like the laying of a foundation stone, it is done "truly and well"; though the T-shaped incision has the sanction of fairly long and general usage. With this method it is easiest to make a perfect union between scion and stock.

The selection of the bud repays for consideration. It is the bud from a flowering shoot that is most satisfactory, and as will be seen from the illustration on this page, the best bud is found towards the basal end of such a shoot, for it is just there that they are the most perfect for the purpose. Lower on the shoot the buds are too dormant and too hard, while on the upper portion they are soft and not sufficiently developed. In the same illustration will be seen the bud prepared for insertion, and in this respect care should be taken to retain the little piece of leaf stalk with the bud. While preparing the bud it must always be remembered that the core, root, or base, as the embryo on the inside is variously termed, is the vital part, and must be treated with the greatest respect. Any injury to this part results in failure. While care is needed to ensure as perfect fitting as may be, and the tie sufficiently tight, but not so as to cause constriction, it is the skilled budder, who can do the work quickly, who succeeds in getting the highest percentage of "takes." On a dull day speed in working is not so essential, but during dry weather the buds and the exposed portion of the stocks both dry quickly, a condition not to be desired.

THE BRIAR STOCK IS BEST.—No longer can the gardener go out and get good stout briars from the highways and byways. During the past we have reaped, but we did not sow, and now are paying the inevitable penalty. This scarcity of briars is widespread, and in the endeavor to overcome it, various stocks, other than *Rosa canina*, have been tried with more or less success. The stock difficulty is more serious with standards. The *Manetti* stock answers very well for bush roses and is readily propagated by cuttings. But for standards none equals our English briar. Lately *Rosa rugosa* has been used a great deal. From the garden point of view the chief objection to it is its slenderness and also that the head often becomes top heavy. Both of these faults could doubtless be removed if the nurseryman would grow the

stocks a year longer before budding them, but I suppose this is asking too much!

More recently a Japanese form of the Siberian *Rosa laxa* has met with favor from the growers. A great point is that it is in a suitable condition for budding much earlier in the season than any other, so that budding is often commenced as early as May—the buds are taken from pot plants—which gives the nurseryman a much longer season than otherwise. This early budding nearly always results in the buds bursting into growth the same season, while one prefers the bud to remain dormant until the following Spring. Though if the *laxa* stock results in sufficient growth of the bud to be properly ripened before Winter sets in, well and good, otherwise serious losses will occur.

LAYERING ROSES.—Many prefer dwarf roses to be on their own roots and insert cuttings later in the year. But there are certain varieties which do not root readily. With these the difficulty can nearly always be overcome by layering, a method which has a deal to recommend it for the garden where only a limited number of fresh plants are required. The layering is carried out much in the same way as with carnations, except that to get the required branch in position a stouter peg is required. For both budding and layering the knife should always be kept as sharp as possible because so much depends on the cuts being cleanly made. The best time for layering is about the last half of July, though, as with other shrubs, it can be successfully performed later.—*The Garden.*

ANNUAL MEETING OF AMERICAN ROSE SOCIETY

(Continued from page 207)

which Greta Kluis, Marie Pavie, were outstanding sorts, the latter a most inveterate bloomer but probably most distinguished among the roses in this new garden were tree roses planted only a year ago last Autumn but with heads of generous spread and 12 to 18 blooms to a plant.

In this little two-day journey the officers of the American Rose Society were fortunate in being able to visit the Rochester Rose Show. For more than one generation has Rochester been known as the flower city but it remained for the young blood of the present day of floral enterprises to put Rochester on the map again rosewise through capable career of this organization started by a master hand within the last two years and stimulated into active service by the rose patron of these parts, Dr. E. M. Mills. They have grown until the Rose Show of this year marks a triumph for scope, extent and quality. Other people have much to learn as do nearly all amateurs with reference to staging roses, but when you can get close to 1,000 people to come out of a night and study your roses (to say nothing of the arduous labors of staging such shows on the part of many of the busy business men and hustling housewives), you have certainly made great progress, and as far as appeared to some of the visitors it would seem as though Rochester would soon take the lead, indeed, if not already there.

John Dunbar of the Park Department with his assistant Mr. Dukelow, used two entire tables to display climbers and species of bush roses in extensive varieties clearly labeled, and outstanding among the exhibits by the Amateur was a huge bowl of Old Gold, a first prize winner. A stately display of Paul's Scarlet Climber and a charming vase of Souv. de Claudius Pernet.

ROBERT PYLE, *President.*

Know thy work, and do it like Hercules. One monster there is in the world, the idle man.—Carlyle.

Departments of Foreign Exchange and Book Reviews

AN AMERICAN'S IMPRESSIONS OF THE CHELSEA SHOW

FOR an American gardener a visit to the Chelsea Show is a rare and happy privilege, an inspiring lesson in the possibilities of making a flower show not only instructive, but beautiful, and also, alas! a source of despair in seeing so many exquisite plants which will not survive our cold Winters and hot Summers.

In recent years we have had in the Eastern United States many fine flower shows of which we are very proud, but even the large size of our biggest national shows had left me unprepared for any show on such a gigantic scale as the 1922 Chelsea Exhibition. We hope that the rapid growing interest in horticulture may make such shows possible with us in the not far distant future.

The show impressed me on account of its great size, its artistic arrangement, the high quality of the exhibits, and the tremendous variety of the plant material used. I liked it all so much that it is difficult for me to try to pick out the best things to comment on, for, with the possible exception of the big Carter clock and the garden surrounded by bright pink dwarf Rhododendrons, I liked everything.

As my greatest interest is in the Iris, I naturally spent much time in Messrs. R. Wallace and Co.'s garden, which received such high honors. This garden was a gem of design and color arrangement, and contained two of the newest Irises of English origin, Asia and Prospero, side by side with the French Ambassador and Souv. de Mme. Gaudichau and the American Lent A. Williamson. Lady Foster, Crusader, and Neptune also appeared to good advantage here, but Dominion had suffered from too hard forcing, and the flower was not characteristic. The Lilies, Azaleas and Regolio Cyclus Iris blended well with the Iris, and made a perfect whole.

The Bunyard Iris garden was also a source of delight to me, and here Ambassadeur, Lord or June, Magnifica and Isolene stood out as giants among some of the older sorts. In the Perry and Whitelegg exhibits, Regolio-Cyclus Iris were the feature.

Perhaps even more fascinating than the Iris gardens were the rock gardens, something we hardly know in America. I liked Mr. Wood's conception best, because it was so very simple that it reminded me of some exquisite bits of wild landscape in some of our New Hampshire or Vermont hills.

Messrs. R. Tucker and Sons' garden contained a greater variety of plant material, and was also very beautiful; in fact, nearly all the rock gardens struck me as being wonderfully artistic, as well as showing many exquisite little plants, and I spent more time with them than I did in some of the formal gardens.

The Rhododendrons were finer than any I had ever seen, the big bushes, in one of the big tents and in Messrs. R. Wallace and Co.'s natural garden being the most striking. To Rhododendron experts the cut flowers were probably equally interesting.

Another group of plants that I admired particularly were the Clematis hybrids exhibited by Messrs. G. Jackson and Co. and one or two others. European gardeners are used to these, but to an American all but one or two varieties are totally new. I do not know how they would grow under our conditions.

We are used to fine displays of Roses in our American shows, and perhaps for this reason the Roses did not impress me so much as some of the other flowers. They were of splendid quality on the first day, and I was glad to see some of the triumphs of two of America's greatest Rose breeders, Dr. Van Fleet and Mr. H. Walsh, both of whom have died within the past few months. The varieties noted were American Pillar, Hiawatha, Paradise, Excelsa and Minnehaha. We are very glad that these are appreciated in England, where so many fine Roses have originated. The American Rose Los Angeles, which won a gold medal at Bagatelle in 1918, was also noted in good condition, as were several other American varieties. The number of varieties exhibited was much greater than in most American shows.

Paul's Scarlet Climber was seen in wonderful form, but I did not think the flowers of the beautiful new Souv. de Claudius Pernet were quite as fine as those staged in our New York show last March.

There was so many new Roses to attract attention that I can comment on only a few. I liked Padre the best, but admired also Rev. F. Page Roberts, the singles Mrs. Oakley Fisher and Pink Delight and the Polyanthas Queen Wilhelmina and La Reine Elizabeth.

The Tulips were gorgeous. I have never seen a display as

fine as Messrs. Dobbie and Co.'s, although I have seen as fine flowers in small quantities in our shows at home. As usual, I liked La Tulip Noire the best of all, and Dom Pedro, Faus and Louis XIV were noted in fine condition in many exhibits.

Carnations surprised me, because I had always supposed the American Carnation was far superior to those grown in Europe. True, there was a liberal sprinkling of American varieties like Enchantress Supreme, Beacon, Benora and White Wonder, all of excellent quality, and also a few of Laddie, which were not nearly so big as with us, but the British varieties seemed equally good. I made no notes on varieties, but Thor impressed me the most. We have no commercially important Carnation of the color of Marion Wilson, which I liked very much. I was also impressed with the fact that at least one breeder was emphasizing the fragrance of his new varieties—a point forgotten by many American breeders in the race after size and productiveness.

The Sweet Peas were as fine as those shown by Burpee in New York, and were shown in greater quantity. The display of Orchids was larger than usually seen with us, with the exception of the recent special Orchid exhibitions put on by Mr. Burrage, president of the Massachusetts Horticultural Society.

These notes have already grown longer than I intended, because I do not know where to stop. I cannot close without mentioning how hungry I got every time I passed Laxton's wonderful strawberries, the like of which I have never seen. We are used to seeing fine vegetable and fruit displays at home, but for this season of the year the Hon. Vicary Gibbs' collection of vegetables was remarkable, and so was Messrs. Bungard and Co.'s collection of Apple varieties, which interested me as showing me many Apples I had read about in your columns in previous years. No American varieties were shown, and they are probably as unsuited to your climate as your varieties are to ours.

I am sorry that you had to treat us to some real American Summer weather during the show week, for it was not only hard on people but on the flowers, many of which were not in good condition on the last day, but my surprise was to see how remarkably they stood up under such adverse conditions. All praise is due to the skillful growers and to the able exhibitors and managers of the show who put on these wonderful shows year after year. I hope I may be able to attend many more of them.—JOHN C. WISTER in *The Gardners' Chronicle* (British).

MANUAL OF THE TREES OF NORTH AMERICA, by Charles Sprague Sargent. Houghton, Mifflin Company, Boston and New York.

It might seem superfluous to mention in an American journal this work, the transcendent merits of which have already been recognized in Europe. An English reviewer, a no mean authority, refers to it as "no doubt the finest work on trees ever published." He declares that "for the lover of trees in North America this work must be indispensable; and in the British Isles, where gardens owe so much to the arboreal vegetation of North America, its value is almost as great."

The first edition, published in 1905 as a revision and condensation into one volume of the author's *Silva of North America*, a magnificent monumental work of fourteen quarto volumes and containing seven hundred and four handsome plates, has since its appearance held complete dominance in its field. This new edition, as an example of the book-making art—a volume that with all its astounding mass of content is of size and structure that actually makes it a practicable manual for field work,—and in composition so sane in selecting and in omitting—is beyond praise. It is absolutely unique in being the well-ripened fruit of most extraordinary genius and powers of work possessed by a man who for forty years has indefatigably studied and worked long hours as the Director of the Arnold Arboretum, by far the best place for a systematic study of the subject. But it may not be known generally that this institutional study and research rest upon a foundation laid in many arduous explorations, such as could be made only by a person of tremendous physical strength and energy, of all the widely scattered portions of the enormous field. The author shows the advantage of thorough acquaintance with the *Silva of Japan* also, which is so closely related to that of temperate North America, and about which he once published an authoritative work. When reference to a genus existing in other parts of the world also seems to be desirable for contrast such reference is made, as for example, in the case of *Ficus*.

The work is profound in its scholarship. The few changes made from classifications in the former edition must meet with universal acceptance. There is commendable insistency upon

strict adherence to the rules of nomenclature adopted by the International Congress of Botanists. Carefulness in the use of common or popular names is inculcated by omitting from the Index such hybrid terms as "Concolor Fir;" but "White Fir" and *Abies concolor* are listed.

As a result of the few changes in classification and the addition of four families and sixteen genera this new edition contains an account of seven hundred and seventeen species of trees in one hundred and eighty-five genera. They are illustrated by seven hundred and eighty-three drawn figures, which, as really good drawings made by experts can do, show more clearly than can reproductions of photographs the details of form, structure and functioning parts. They reveal, as do other evidences of hard work, the felicity with which Professor Sargent has attached to himself capable and devoted helpers.

The book has of course not been intended primarily for the nurseryman or the landscape designer. But a careful use of it by them would often be well rewarded. Exotic trees, with the exception of the few that have become naturalized as "escapes" and such important "introduced" trees as the White Mulberry and the Black Mulberry, are not given place. Distinct species of great importance to the nurseryman, like the Bechtel Crab and the so-called Bartram Oak are given appropriate mention; while sporting forms like Teas' Weeping Mulberry and the Weeping Hemlock and cultivated seminal varieties of the Hemlock, as well as sports in coloring like Koster's Blue Spruce are not given space; but the author has seen fit to refer to Dogwoods with rose-colored or pink involucres which have come to be admitted as now constituting a variety by themselves, and to two other varieties, *pendula* and *xanthocarpa*. The planter of trees is told of the important difference between the northern form and the southern form of *Magnolia glauca* and between *Amelanchier canadensis* and *A. lewis*, the latter being the more desirable of the two Service Berries. The European planter is informed that the Red Oak is generally more successful in his continent. Much other information has been barred by limitations of space, evidently much against the author's will. He has contented himself with calling attention only in the most prominent instances, without the extravagance of the catalogs, to especial beauty. He does give the origin of the name where that helps to know better the subject, as it often does. The commercial uses of the various genera and species are wisely set forth, succinctly but thoroughly, as is notable, exemplified by the eight lines treating of this topic under *Tilia*. Minor matters that might be missed by the inquirer for information in making use of certain trees for planting, such as the unwisdom of placing a Soft Maple or a Box Elder into a certain site, have had to be left to books of landscape gardening.

But the book is almost incomprehensively complete and thorough. Perhaps the most wonderful part of it consists of the one hundred and fifty-two very compact pages describing, with exact botanical detail, one hundred and fifty-three species of *Crataegus* each illustrated by an exquisitely nice drawing. In fact, in treating of silvan growth native to the wide field covered nothing seems to have eluded notice: *Magnolia acuminata* var. *Sarg.*, for example, is noted as "having been preserved in gardens for more than a century and not re-discovered as a wild plant until 1913." To emphasize the accuracy of the work as a whole the present writer would modestly add that he has happened upon only one misprint, and that a trifling one, in the Index, "Oak, Mossy Cap," obviously intended for "Oak, Mossy Cup."—F. B. M.

GARDENING WITH BRAINS by Henry T. Finck, Harper and Brothers, New York.

In both form and content this volume is the strongly characteristic issue of the mind and personality of the man who for forty years has been on the staff of the New York *Evening Post* as "Musical and Epicurean Editor" and has published a book named *Food and Flavor*. It is the resultant of a very lively mixture of almost rollicking humor, uniquely keen powers of mental and physical enjoyment, intimate friendship with such persons as Luther Burbank, John Burroughs, Edith Simonds and well-known and originating seedmen and horticulturists,—all persons through whose arteries pulsates intense love of Nature,—and experience in gardening in one of the least favored regions of the country, Northern Maine. So it was *spirit* as well as with brains that were written these entertaining pages that treat of seeds and tillage, of the most savory vegetables and the importance of their rapid transit to the table, of what are the flowers most worth while and how to rescue them and the vegetables and the fruits from their enemies, of what are the most luscious and most wholesome fruits already available and of what may be hoped for in the way of obtaining fruits still more luscious and

It is in this last phase of the general subject that the most interesting part of the book is to be found. Green manuring and intensive cultivation have full appreciation, the "fragrant soul of flowers" is descanted upon most eloquently and a slight attempt is made to show respect for creative design and pictorial beauty in the garden,—not altogether successful, to be sure, for the author's taste in this matter is a trifle bizarre, as is witnessed by his fondness for "rain-

bow corn" and blue poppies. But for Luther Burbank his enthusiasm is so great as to make one almost believe that this "plant wizard's" work is nearly as great, if not quite as great, as it is made to appear in his own books and in the many eulogistic books that other persons have written about him. The chapters, *The Joys of Creative Gardening*, *Educated Strawberries* and *Burbank Plums*, and *Commercial Value of Burbank's New Creations*, are powerful. They defend with a convincing array of facts and with reasoning, all set forth feelingly, in the conclusion of this very entertaining, instructive and handsomely made book.—F. B. M.

OPPORTUNITIES OUT-OF-DOORS, by Edward Owen Dean. Harper and Brothers, New York.

This is one of a series of little books that seem to be all worth while. Others are *Opportunities in Engineering*, *Opportunities in Aviation*, *Opportunities in Farming*. This particular volume considers opportunities in *Construction*, in *Forestry*, in the *Lumber Industry*, in *Tree Surgery*, in *Rural Motor Express*, in *Collecting and Growing Medicinal Plants* and in *Landscape Gardening*. It is accordingly a work that should be of interest to many readers of this periodical and should be of help to all persons, old and young, in interpreting that call that to the dwellers in cities often becomes very, very strong. It is written from the conviction that "one of the saddest sights in life is that of a man in the wrong job." But it abounds in cautions; all prizes of the professions treated were first carefully discussed by the author with men actively engaged in those respective callings. The natural aptitudes and the requirements for success are stated no less frankly and with no less seriousness than are the attractions.—F. B. M.

BULB GARDENING, by Mary Hampden. Charles Scribner's Sons, New York.

This is a brave and spirited attempt to treat a very brief subject succinctly and yet comprehensively; bulbs for growing indoors as well as the hardy ones are included. Consequently the discussions of most topics is necessarily rather sketchy; but it is skilful. For a brief treatment the chapters given to *Hyacinths*, *Tulips*, *Daffodils* and other *Narcissi* are quite satisfactory. Under *Iris*es the author does well to include in this work the rhizomatous and the fibrous-rooted also; it is to be regretted, however, in view of the great widening of the class of *Iris germanica*, that she puts this species among those that are suitable for damp soil beneath trees. Concerning them the book gives only a bare intimation of their remarkable developments made during the past few years. As to their culture is it not poor advice to state that "three inches deep is a good average" and that "in very light sandy borders a greater depth is often desirable"? This is apt, even in sandy soils, to cause rot at the base of the leaves, as certainly would "a layer of old cow manure in October."

The chapter on *Snowdrops*, *Crocuses* and *Chionodoxas* is a fine one and makes more poignant the chagrin felt by American gardeners in not being permitted to import the first and the last of these delightful diminutive flowers. The section devoted to *Lilies* is the most nearly complete and most satisfactory of the entire book. It touches upon the wild European corn flag, or *Gladiolus communis*, and contains the all too brief mention of the *Hemerocallis*. Its one deficiency lies in not distinguishing those lilies that form roots above the bulb from those that feed below the bulb only. A valuable service has been done by putting into systematic and compact form an appreciation of the many minor bulbous flowers, such as the anemones, fritillaries, ranunculuses, alliums, ornithogalums, meadow saffrons, cyclamens and Christmas roses. Likewise deserving of thankful appreciation are Part II, which is a summary treatment of the multifarious glass-house bulbs, and Part III, which enumerates, with the most necessary directions for their cultivation, the half-hardy bulbs, such as the tuberous *Begonia*, the *Gladiolus* and the *Dahlia*, not to mention more than a score of others.

Considering the wide range covered one must recognize that the author has been wonderfully attentive to this interesting class of flowering plants which, though very popular, is not yet generally made use of as it ought to be, for in addition to being so diversified in beauty it is true, as an old book on gardening tells, that "in a sense bulbs are of more easy culture than any other class of plant, as, the germ being previously formed, and the nourishment provided in the body of the bulb, it is only necessary to supply heat and moisture to cause these to develop."—F. B. M.

Boston, Mass.: Robert Cameron, chairman.

PLANS FOR BOSTON CONVENTION, SEPTEMBER 12, 13, 14, 15

A MEETING of the Boston branch of the National Association of Gardeners was held at Horticultural Hall, Boston, on Friday evening, June 30, about 35 members present, including a number from Manchester, Prides Crossing, Ipswich and other North Shore resorts. Robert Cameron, president of the N. A. G., presided and called the meeting to order. W. N. Craig, general chairman of the convention committees, spoke of the duties which would fall on each committee, and the members expressed a willingness to see the same carried through.

Meetings will be held at Horticultural Hall, at the corner of Huntington and Massachusetts Aves., which is a short car ride from the Back Bay Station of the N. Y., N. H. and H. R. R., and the Trinity Place Station of the Boston & Albany R. R. A constant stream of cars pass the hall as the heart of Boston is only a few minutes distant. In very close proximity to Horticultural Hall are such notable buildings as Symphony Hall, the New England Conservatory of Music, the Christian Science Temple, Boston Museum of Fine Arts, Y. M. C. A., etc. Our hotel headquarters will be only a few minutes' walk from Horticultural Hall.

The first two days of the convention will be devoted to business, and none will be transacted on the two closing days. For the opening day speakers will include the Mayor of Boston, the president of the Massachusetts Horticultural Society and one or two others of horticultural prominence. The annual banquet will be held on the second evening and some very unique features will be arranged for this occasion.

On the morning of the third day a large number of automobiles will start early for the famed North Shore of Massachusetts and several of the finest gardens in Beverly Farms, Manchester, West Manchester, Prides Crossing, etc., will be visited, and passing on to Ipswich, the convention party will be the guests of Mr. and Mrs. R. T. Crane at a real New England clambake. Later, the extensive gardens at Castle Hill Farm, the 2,500 acre estate over which Robert Cameron presides, with its five miles of coast line and rolling dunes of white sand, will be inspected. On the return journey to Boston the Cedar Acre gladioli and dahlia gardens of B. Hammond Tracy will be visited, and Mr. and Mrs. Tracy will entertain the visitors; places of historic interest will be passed en route to Boston.

On the last day of the convention the noted Arnold Arboretum with its matchless collections of trees and shrubs, and part of Boston's parkways will be inspected. Later, visitors will be taken to Cambridge where under the shadow of Harvard College the world-famed collection of glass flowers in the Agassiz Museum, will be seen. Leaving Cambridge, historic Lexington and Concord will be visited, and later the famous Walter and Henry S. Hunnewell estates in Wellesley with their wonderful specimens of trees and shrubs, will be inspected. Other points of interest will be taken in to fill out a most interesting and well varied day.

It was voted to send a letter of sympathy to Mrs. Thomas Hatton of New London, Conn. Mr. Hatton was a well known and much esteemed member of the N. A. G. A set of By-Laws for the use of local branches was discussed and adopted; also amendments relative to the reserve fund of the N. A. G. Another meeting will be held on Friday evening, July 28 at Horticultural Hall.

NEW DIRECTOR

President Robert Cameron has appointed George H. Pring, Horticulturist, Missouri Botanical Garden, St. Louis, to serve as director until 1924, to fill the unexpired term of Albin Martini, formerly of Cedar Rapids, Iowa.

COURSE FOR TRAINING GARDENERS

The attention of the members of the association is called to page 209 of this month's issue of the GARDENERS' CHRONICLE on which the announcement of the course for training gardeners, adopted by the association, in cooperation with the Massachusetts Agricultural College, is made.

NEW YORK PARTY TO CONVENTION

It is planned that members in and around the locality of New York who are going to attend the Boston convention will leave as a party Monday evening, September 11, by the Boston outside line, and will arrive in Boston on the following morning, the opening day of the convention, Tuesday, September 12.

The final convention program and complete details regarding hotel headquarters, and to whom to apply for hotel reservations, will be made in the August issue of the GARDENERS' CHRONICLE.

NEW MEMBERS

The following new members have been recently added to the membership roll of the association: Richard Rogers, Stamford, Conn.; Charles Linek, New York, N. Y.; Eric H. Wetterlow, Manchester, Mass.; Einar Schacht, Westbury, L. I.; James Morton, Beverly, Mass.; P. S. Van Baarda, Boston, Mass.; Wm. Williams, Elberon, N. J.; Alexander P. Dewar, Boston, Mass.; Victor E. Nelson, Boston, Mass.; Thomas W. Carr, New York, N. Y.; Thomas Whyte, Topsheld, Mass.; Allen Rainsford, Armonk, N. Y.; Gaston Gaberel, New York, N. Y.; Thomas H. McNamara, Kennett Sq., Pa.; Samuel Scott, New Haven, Conn.; John I. McLane, New York, N. Y.; James Finnie, Boston, Mass.

RAIN WHEN YOU WANT IT

50 Foot Line Costs Only \$19.75

Comes in sections that go together with Quick Acting Couplings

One man can set it up in 20 minutes

Or take it down, move and set up again in 30 minutes.

Waters every inch of 2500 square feet uniformly.

Nothing to get out of repair.

Attaches to hose. Pressure 20 lbs. or more. Usually set on 3/4" or 1" pipe posts, 3 to 4 feet above ground.

ST. LOUIS ASSOCIATION OF GARDENERS

CAMPBELL Wednesday nite mach 19 ..

The first outdoor meeting of the season was held at the Estate of S. Plant, at Clayton, Mo., June 4th. After a short business session the members were conducted over the grounds by Mr. Plant and Wm. Schoenhofer, his gardener. It was explained that ten years ago this estate was practically treeless and the soil of such a tenacious clay nature that it seemed a rather hopeless proposition for its development into a country estate.

It is now, however, one of the finest estates in the vicinity of St. Louis. The luxuriant growth of the trees are largely due to the use of dynamite previous to planting and subsequent cultivating, mulching and care. This place is an object lesson to those who believe that it takes a lifetime to grow trees of sufficient size for shade and comfort.

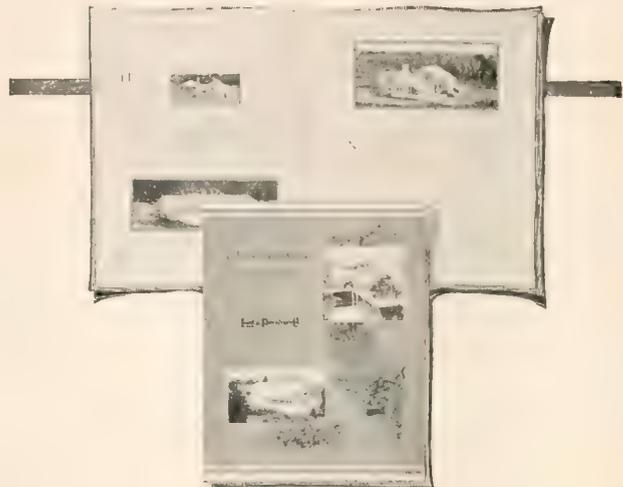

After the inspection of the premises a luncheon was served.

The July meeting was held at the establishment of C. E. DeWever, Olivette, Mo. Mr. DeWever is a commercial grower, specializing in French hydranges and gladiolus. A special demonstration of his practice of cultivating with a small tractor and method of irrigation was given for the benefit of the gardeners, which proved both interesting and instructive. Before departing a lunch was served.

L. P. JENSEN,
Cor. Secretary.

THE CLEVELAND HORT. SOCIETY

The above society held its first monthly field trip of the year on June 22. The weather conditions were ideal, and about fifty of the members turned out. The trip

Superintendents and Gardeners This Specially Interests You

It specially interests you, because it gets right down to brass tacks on the five standard size greenhouses which most of you mostly want.

Each subject is complete in its exterior and interior photos with section, plan and right-to-the-point description.

Altho so decidedly practical, it is, nevertheless, so beautifully printed and attractive that it will surely appeal to your employers.

Here are some of the subjects treated.

1. The Three Bench House
18 feet wide.
2. Four Bench House
25 feet wide.

3. General Purpose Four Bench House
Giving You Four Compartments.
4. Plant House and Wings with Four Compartments.
5. The Sectional Construction
Its Ease of Enlargement.
6. The Construction Fully Described.
7. A Rose House 130 Years Old.
8. The Most Greenhouse
For the Least Money.

Having prepared it all with you particularly in mind, we want to make sure you surely get a copy. Likewise if you wish, your employer also. Send us your and their name and address and we'll promptly mail it.

was made in autos, commencing from the estate of F. F. Prentice, Mayfield Road, at ten o'clock. R. P. Brydon, superintendent to Mr. Prentice, welcomed the guests and showed them over the extensively developed grounds. The wonderful masses of Japanese iris were greatly admired, as were also the formal gardens. The greenhouses were gone through where everything was found growing in perfect condition. The French hydrangeas and liliums in bloom were a source of much admiration.

The estate of J. L. Severance was next visited, where A. Brown, the superintendent, led the members through the greenhouses and some beautiful specimen ferns were seen. The Fall crops were all growing splendidly. The other gardens on the estate were inspected with much interest. The evergreen plantings here are most artistically arranged and caused considerable comment.

The C. C. Bolton estate was the next stop, and Mr. Knapp, superintendent, showed the men the rose and formal gardens, which were much admired.

F. E. Drury's estate at Gates Mill was the next one taken in, where J. H. Francis,

THE MORRIS NURSERY CO.
1123 Broadway New York, N. Y.

superintendent, conducted the delegation through the range of glass. Everything was found to be in splendid form; the ripe melons in the houses drew a lot of attention, but it was too hot to remain there long. A walk through the new vegetable garden edged by perennial borders and terraced up to the rose garden by cobble stone walls was of great interest, and then back through the barns where the thoroughbred Guernsey cattle were visited which received equally as much interest as the horticultural departments had.

Charm Falls was the next point, the autos driving along the beautiful river road to the estate of E. S. Burke, Jr., where Mr. Fisher, superintendent, gave the men a real welcome. After lunch the new range of glass was inspected where everything was coming along in fine shape. A walk up the winding drive which follows through a valley was very beautiful; the natural planting which has been done during the past two or three years looks as if it has always been there.

A drive in the autos along the private driveways which are almost five miles in length was indeed interesting, stops being made at different points along the way. Mr. Fisher explained the development of the estate, the cobblestone rockwork used mostly as retaining walls and covered with low growing plants and shrubs, appeared as though they had always been a part of the place.

The last stop was made at the estate of W. T. White where the formal gardens were most favorably commented on. The member... only one going in his own direction, well satisfied with what he had seen and heard during the day.

W. J. BRUCE, Secy.

Prepare Now for the Hot Dry Days

No need to worry about the long, hot, rainless days if you have a Dayton Rotary Oscillating Sprinkler ready. It makes rain when you want it. It sprinkles every foot of ground in a circle, or half circle, of 6 feet to 80 feet.

It is better for your lawn and plants and more saving of water than sprinkling with a hose. The Dayton operates on any water pressure from 15 pounds up. If your local dealer cannot supply you, order from us direct. \$8 1/2. N. Y.

H. A. Robinson & Company, 128 Water Street, New York

SOLD BY SEEDMEN IN CANADA FOR OVER THIRTY YEARS

Hammond's Slug Shot
Grandfather used it for potato bugs. Father uses it. Mother uses it on her roses.
This year I am using it in my garden.

"HAMMOND'S SLUG SHOT"

Used from Ocean to Ocean

A light, composite, fine powder, easily distributed either by duster, bellows, or in water by spraying. Thoroughly reliable in killing Curraut Worms, Potato Bugs, Cabbage Worms, Line Slugs, Saw Flies, etc., and it is also strongly impregnated with fungicides. Put up in Popular Packages at Popular Prices. Sold by Seed Dealers and Merchants.

**OF INTEREST TO COUNTRY
ESTATE OWNERS**

The National Association of Gardeners takes this opportunity to place its Service Bureau at the disposal of owners of country estates when requiring competent gardeners, in the capacities of superintendents, head gardeners or assistant gardeners—thoroughly qualified in every particular to assume the responsibilities the positions call for—gardeners truly efficient in their profession.

The Bureau is maintained entirely at the expense of the association and makes no charge to the employer it may serve or to the member it may benefit.

NATIONAL ASSOCIATION OF GARDENERS

M. C. Ebel, Secretary
286 Fifth Ave. New York

This association is in no sense a trade union organization, but includes in its sustaining membership owners of some of the foremost country estates in America.

SPRAYING
is as
Essential as Fertilizing

Successful cultivation demands a knowledge of the habits of plant insects and diseases, and the proper remedies for their control.

APHINE, an effective remedy against all sap sucking insects infesting flowers, fruits and vegetables, is free of the disagreeable odors and features of most insecticides. It invigorates plant life and is unexcelled as a wash for decorative plants. Aphine will not injure the most tender flower or foliage.

FUNGINE is an excellent remedy for mildew, rust, and other blights. It is readily soluble in water and contains no sediment. Fungine does not stain the foliage but cleanses it.

VERMINE is a soil sterilizer and vermicide. It destroys cut, wire, eel and grub worms, maggots, root lice and ants, and will protect your gardens and lawns from ravages under the soil.

There is but one convincing way for you to become familiar with the merits of these products and that is to try them out for yourself. It will prove worth while.

Sold by dealers in various sizes.

BURPEE'S SWEET PEAS

The Burpee Early Flowering Sweet Peas are recognized as leaders in their various colors and they are grown extensively by all florists who demand the very best.

The careful hybridization work carried on at Burpee's Fordhook Farms in Pennsylvania, the growing of the seed crops on Burpee's Floradale Farms in California, and our extensive indoor and outdoor trials give us a unique opportunity to supply the florists with the very best that can be had in Sweet Peas. Everything possible is done to insure the quality of Burpee's Sweet Peas.

NOVELTIES

BURPEE'S ORANGE. In every way a beautiful variety of true glowing orange self with standard and wings of immense size. Awarded Certificate of Merit at the International Flower Show, New York, March, 1921. Trade packet, \$1.00; oz., \$5.00; ¼ lb., \$15.00; lb., \$50.00, postpaid.

CHEERFUL. The large pinkish cerise flowers are an entirely new shade in the Early or Winter Flowering Sweet Peas. Awarded Certificate of Merit at the International Flower Show, New York, March, 1921. Trade packet, \$1.00; oz., \$5.00; ¼ lb., \$15.00; lb., \$50.00, postpaid.

SUNBURST IMPROVED. The color is a pleasing and attractive shade of rich salmon-pink. The large flowers which are borne on long stems grow vigorously and bloom freely. Oz., \$1.00; ¼ lb., \$3.00; lb., \$10.00, postpaid.

MRS. WARREN G. HARDING. "The Harding Blue." A deep shade of silvery blue, pure throughout with no suspicion of mauve or rose. The flowers are immense in size with a broad and much frilled standard. Trade packet, 50 cents; oz., \$2.50; ¼ lb., \$7.50; lb., \$25.00, postpaid.

MRS. KERR. "The Best Early Flowering Salmon." Mrs. Kerr has created a sensation whenever exhibited as it is a flower of wonderful size in a most popular shade of clear and rich salmon. Trade packet, 50 cents; oz., \$2.00; ¼ lb., \$6.00; lb., \$18.00, postpaid.

WHITE STAR. A first-class black-seeded white without any suspicion of pink or other coloring. Trade packet, 50 cents; oz., \$2.00; ¼ lb., \$6.00; lb., \$18.00, postpaid.

WHITE

SNOWSTORM IMPROVED. The flowers are of large size, best form, and long stems. Oz. 80 cts.; ¼ lb. \$2.40; lb. \$8.00, postpaid.

Early Sankey. A black-seeded white, which is a variety of the Silver Medal. Oz. 60 cts.; ¼ lb. \$1.80; lb. \$6.00, postpaid.

CREAM

Lemon Beauty. A variety of the cream color with flowers of great size. Oz. \$1.00; ¼ lb. \$3.00; lb. \$10.00, postpaid.

Canary Bird. A variety of the cream color with flowers of great size. Oz. 50 cts.; ¼ lb. \$1.50; lb. \$5.00, postpaid.

PICOTEE

Daintiness. Pure white edged with rose. Oz. 60 cts.; ¼ lb. \$1.80; lb. \$6.00, postpaid.

Exquisite. The ground color is a soft shade of cream. Oz. 50 cts.; ¼ lb. \$1.50; lb. \$5.00, postpaid.

CREAM-PINK

DAYBREAK. A pleasing shade of rich rose-pink on cream ground. Oz. 60 cts.; ¼ lb. \$1.80; lb. \$6.00, postpaid.

LIGHT PINK

Lovefulness. A variety of the light pink color with flowers of great size. Oz. 60 cts.; ¼ lb. \$1.80; lb. \$6.00, postpaid.

Peach Blossom. A variety of the light pink color with flowers of great size. Oz. \$1.00; ¼ lb. \$3.00; lb. \$10.00, postpaid.

DEEP PINK

CHEERFUL. The very finest pink. Described under *Novelties*. Trade packet \$1.00; oz. \$5.00; ¼ lb. \$15.00; lb. \$50.00, postpaid.

ENCHANTRESS. A bright rose-pink, best form and wings. Oz. 60 cts.; ¼ lb. \$1.80; lb. \$6.00, postpaid.

Pink Beauty. The color is a soft rose-pink with a suffusion of rose. Oz. 50 cts.; ¼ lb. \$1.50; lb. \$5.00, postpaid.

ROSE QUEEN. A pleasing shade of rich pink with a suffusion of rose. Oz. 60 cts.; ¼ lb. \$1.80; lb. \$6.00, postpaid.

ROSE

Fordhook Rose Improved. A variety of the rose color with flowers of great size. Oz. 50 cts.; ¼ lb. \$1.50; lb. \$5.00, postpaid.

Rosebud. A variety of the rose color with flowers of great size. Oz. 50 cts.; ¼ lb. \$1.50; lb. \$5.00, postpaid.

ZVOLANEK'S ROSE. A variety of the rose color with flowers of great size. Oz. 80 cts.; ¼ lb. \$2.40; lb. \$8.00, postpaid.

CRIMSON

EARLY KING. The finest variety of the crimson color with flowers of great size. Oz. 60 cts.; ¼ lb. \$1.80; lb. \$6.00, postpaid.

ORANGE-SCARLET

GLITTERS. No variety we know of approaches Glitters in richness, brightness and live-fire effect. The large bold flowers are a rich orange-scarlet. Oz. \$1.00; ¼ lb. \$3.00; lb. \$10.00, postpaid.

ORANGE

BURPEE'S ORANGE. A glistening pure orange. Trade packet \$1.00; oz. \$5.00; ¼ lb. \$15.00; lb. \$50.00, postpaid.

FLAMINGO. A particularly attractive and pleasing shade of orange. Oz. \$1.00; ¼ lb. \$3.00; lb. \$10.00, postpaid.

SALMON

MRS. KERR. "The Best Early Flowering Salmon." Described under *Novelties*. Trade packet 50 cts.; oz. \$2.00; ¼ lb. \$6.00; lb. \$18.00, postpaid.

Apricot. Glowing deep salmon self with a faint suffusion of orange. Oz. 80 cts.; ¼ lb. \$2.40; lb. \$8.00, postpaid.

CERISE

Fire King. A variety of the cerise color with flowers of great size. Oz. 70 cts.; ¼ lb. \$2.10; lb. \$7.00, postpaid.

Generous. A variety of the cerise color with flowers of great size. Oz. 60 cts.; ¼ lb. \$1.80; lb. \$6.00, postpaid.

ILLUMINATION. Glowing salmon-cerise with a faint suffusion of orange. Oz. 80 cts.; ¼ lb. \$2.40; lb. \$8.00, postpaid.

LAVENDER

Lavender King. A variety of the lavender color with flowers of great size. Oz. 60 cts.; ¼ lb. \$1.80; lb. \$6.00, postpaid.

BLUE

MRS. WARREN G. HARDING. "The Harding Blue." Described under *Novelties*. Trade packet 50 cts.; oz. \$2.50; ¼ lb. \$7.50; lb. \$25.00, postpaid.

CHEERFUL
Burpee's New Sweet Pea, a rich shade of rose

BLUE-BIRD. A true self blue of large size carried on long stems. Oz. 60 cts.; ¼ lb. \$1.80; lb. \$6.00, postpaid.

True Blue. A charming shade of true blue. Oz. 80 cts.; ¼ lb. \$2.40; lb. \$8.00, postpaid.

Blue Jacket. A rich navy-blue self with flowers borne on long stems. Oz. 80 cts.; ¼ lb. \$2.40; lb. \$8.00, postpaid.

MAUVE

Mauve Beauty. The color is a pleasing shade of rosy mauve. Oz. 60 cts.; ¼ lb. \$1.80; lb. \$6.00, postpaid.

PURPLE

Glorious. An early flowering Royal Purple. Oz. 50 cts.; ¼ lb. \$1.50; lb. \$5.00, postpaid.

ART SHADES

Fairy Queen. Blush-pink with pale salmon suffusion and dark veinnings of rose. Oz. 60 cts.; ¼ lb. \$1.80; lb. \$6.00, postpaid.

BICOLOR

Yamawa. Bright pink with a suffusion of blue. Oz. 50 cts.; ¼ lb. \$1.50; lb. \$5.00, postpaid.

FORDHOOK PINK AND WHITE. Bright pink with a suffusion of white. Oz. 50 cts.; ¼ lb. \$1.50; lb. \$5.00, postpaid.

Columbia. A variety of the bicolor color with flowers of great size. Oz. 80 cts.; ¼ lb. \$2.40; lb. \$8.00, postpaid.

STRIPED

Aurora. A variety of the striped color with flowers of great size. Oz. 80 cts.; ¼ lb. \$2.40; lb. \$8.00, postpaid.

Things and Thoughts of the Garden

WILLIAM N. CRAIG

LIBRARY
NEW YORK
BOTANICAL
GARDEN

MANY moisture loving plants, commonly regarded as semi-aquatic, do remarkably well in the average perennial border, especially where they have a generous soil and can have an occasional watering in times of drought. A few of these plants are *Senecio clivorum*, *Lobelia cardinalis*, *Lythrum roseum superbum*, *Iris Kämpferi*, and thalictrums in variety. *Senecio clivorum* is a very robust subject and while its real home is on the margin of ponds, it succeeds well in the herbaceous border. It is somewhat coarse but flowers at a time when there is no great variety in the hardy garden, excepting phloxes of the *paniculata* type. The spikes of *Lobelia cardinalis* grown in dry land I have found keep much better in water than those from boggy locations. *Lobelia siphilitica* also makes an excellent border plant and the Chelones, usually associated with swamps, also succeed extremely well. Even the so-called water forget-me-not, *Myosotis palustris*, will flower all Summer in a border if it can enjoy a little shade.

Flowering shrubs in August are not abundant and the Buddleias are very welcome. They have so far proved immune from both insect pests and diseases and are of such easy culture that everyone should try a few plants. They should not be pruned until Spring, and then if cut down near the ground, they will do their best. If pruned back in late Fall, I find that they Winter poorly. Plants have withstood a Winter minimum of 20 degrees below zero without injury even when unprotected. Of the various forms of *B. variabilis* in commerce, I consider *magnifica* by far the best. Its racemes are much more freely produced than on *Veitchiana* and the plant has a better habit. *B. Eva Dudley*, a hybrid between *Asiatica* and *magnifica*, blooms in October out-doors. It is intermediate in color but does not flower as abundantly as either parent. It is useful in the flower garden in Fall when flowers are becoming scarce.

The various bush honeysuckles are always very attractive while in fruit. The bulk carry scarlet fruit but some are golden and one carries berries similar to blueberries in color; these latter, however, are somewhat short lived. The scarlet fruited forms are much the most striking and if one could only have them for the holidays, how effectively they could be utilized! I consider *Morrowi* much the finest of the red-fruited section, and it always carries a greater wealth of fruit than any other *Lonicera*. Many people purchase what purports to be *Morrowi*, raised from

seed. These plants generally run up as tall as *tatarica*. The true *Morrowi* rarely exceeds six feet in height, but will spread fifteen to twenty-five feet across if allowed space. If given room to show its individuality, there is no more beautiful shrub either in flower or fruit. Propagation by cuttings in Summer is very easy.

* * *

How long will potatoes succeed in the same soil? It is generally considered suicidal to plant two successive seasons, and we are told of the absolute necessity of crop rotations if we want a satisfactory yield. I have in mind a good sized plot which has just produced its seventh crop of potatoes without change, and the last crop was far the heaviest and cleanest of the lot. After harvesting each year Winter rye has been sown on the plot and allowed to make considerable growth in Spring before being plowed in. A commercial potato fertilizer has been used at planting time, while a top-dressing of nitrate of soda has been given when the plants were four to five inches high. No manure whatever has been used for seven years. The plants have had three sprayings each season. The varieties grown have been Spaulding Rose, Irish Cobbler, and Green Mountain. Those who want potatoes but have only limited land and cannot give rotations, commonly advocated, may gain comfort from this experience.

* * *

Much has been published about the waning popularity of the Baldwin apple of late. Some growers class it as too tender; others that it only crops in alternate years, and we are further told, that its color and flavor are inferior to some other varieties. In so far as cropping is concerned, I find Baldwin still a top notcher, and while it lacks the brilliancy of Macintosh Red and Wealthy, it is less easily bruised than these varieties, far less susceptible to skin fungus and a vastly better keeper. Macintosh is a beautiful apple but its season is Fall and very early Winter, while Baldwins may be kept in good condition until the end of June. Both Macintosh and Wealthy need several sprayings after the fruits set if freedom from fungus is wanted, and in this connection dust spraying is proving more effective than liquid spraying at a great saving in time and labor. I think the time is not far distant when aeroplanes can be sent over orchards and shade trees to send clouds of dust over them as a cure for both insect pests and diseases, as was demonstrated in England the past season.

Speaking of insect pests, it is interesting to note that near Boston, where the gypsy moth got its start in America and where millions of dollars have been spent in combating it, that this major pest is scarcer than ever before, this being due to the prevalence of the wilt disease, the work of parasitic foes and unfavorable climatic conditions, for all of which we are profoundly grateful. The brown tail moth is extinct except in a few scattered localities. The elm leaf beetle, which came as a plague in 1900, threatened to wipe out all our elms and finally disappeared, has come back in places, but is not numerous. The oak leaf roller threatened to destroy all our oaks six or eight years ago, but is now rarely met with. The San Jose scale, which was to clean out all our orchards, is still with us but is gradually dwindling. It taught us the necessity of dormant spraying and, as a result, we have much better orchards. The European corn borer is destructive now but it will, before long, be controlled by parasites. Other pests there are in Massachusetts but where tons of arsenate of lead were used a decade ago, 100 pounds suffices for protection now, and if we only had more birds, our insect fights would be still more lightened.

* * *

The latest document from the Federal Horticultural Board is pitifully weak when examined. The eminent array of Government and State officials dare hardly criticize the hand that feeds them, knowing full well that if they did so, they would speedily suffer decapitation, and the various nurserymen who applaud the beneficent (to them) Quarantine 37 do so, not because they are terrified at the possible introduction of a few more bugs but because the F. H. B. functioning as a tariff board accords them almost complete protection from foreign sources, and that means much higher prices for home raised plants to the ultimate consumer, and of course this is the only legitimate way to build up "a more truly American Horticulture!" Dr Marlatt's special committee has given the F. H. B. the generous coat of whitewash desired, but their latest exploits will only tend to strengthen opposition to the board as at present constituted, and further camouflaging on their part will be necessary if they hope to hoodwink those who remain unconvinced that a board of scientific theorists appointed to protect us from plant pests and diseases should appoint themselves a tariff legislative body.

* * *

Some years ago when *Watsonia Ardernei* was first introduced from South Africa it attained some popularity as a greenhouse plant. Of late it is rarely seen. In Florida, California and other warm States these beautiful bulbous plants are very popular as garden plants and flower over a long season. My friend, F. W. Fletcher of Orlando, Fla., sent me some bulbs last Fall. These were pot-grown and flowered beautifully, the colors being mainly peach pink and pure white. The spikes are well branched and carry as many as 50 or more flowers each. They grow somewhat taller than gladioli, want similar culture and are fine for cutting. For use in groups of flowering plants at our Spring shows they would be excellent. I do not remember to have seen any at recent shows. Bulbs are obtainable in abundance in both Florida and California. *Watsonias* might also prove a profitable bench crop for commercial growers to try in a moderate way, cutting them when the first two or three flowers open.

* * *

The scarborough hily (*Vallota purpurea*) is rarely seen on city estates. It is one of those subjects which is usually better grown and flowered by small amateurs than by professional gardeners, and quite commonly at agricultural fairs in Massachusetts in September or early

October, splendidly flowered plants in large pots or tubs are exhibited, carrying anywhere from two dozen spikes upwards. Those who flower them so successfully usually Winter them in a light cellar, and a point to remember is that while they are closely allied to *Amaryllis*, they are evergreen leaved and must never be dried off. Furthermore, they resent disturbance at the roots and flower most profusely when bulbs are crowded and receptacles matted with roots. In this respect they are not dissimilar from Nerines. There is a pure white form of *Vallota* in cultivation and several varieties of the scarlet type, the finest being called *magnifica*. *V. purpurea* was introduced from South Africa in 1774 and the plant is named after M. Pierre Valot, a French botanist who wrote a description of the royal gardens as long ago as 1623. For the successful culture of *Vallota*, it is necessary to cover bulbs several inches deep and bed them well in sand. It will take a year or two for them to thoroughly establish themselves. Well grown and bloomed plants, carrying numerous spikes two to three feet in height, are most attractive.

* * *

Greenhouse tomatoes have this season been more troubled with mildew than for many years owing to the prolonged spell of hot, rainy weather in June, with many dark days with an atmosphere reeking with humidity. A great many florists grow tomatoes as late Spring and Summer crops and nearly all private estates where there are greenhouses plant quite a number. The value of dust over liquid spraying has been clearly proved this season. I have used 80 per cent sulphur and 20 per cent lime, and this has controlled mildew much better than Bordeaux mixture or sprays containing sulphur. At the Lexington Field Station, managed conjointly by the Boston Market Gardeners' Association and the Massachusetts Agricultural College, a large number of varieties, mostly of British origin, are being tested under glass this season, and the one which seemed to me to be the best all round sort was Lister's Excelsior, a 1917 introduction. Comet also showed up well, but the crop was not, owing to mildew attacks, a normal one.

* * *

What is the best producing and most disease-proof asparagus? This is a question frequently asked and it is an important one. There has been a steady improvement in varieties and types of late years and much has been accomplished by selection. Not many years ago Palmetto, Giant Argenteuil and Conover's Colossal were the stand-bys. These varieties are still largely grown but Reading Giant has forged to the front rapidly of late years. Now it in turn seems destined to play second fiddle to Martha Washington. There are several Washingtons on the market, which is unfortunate, as the average amateur or private gardener does not know whether to buy Mary Washington, Martha Washington or Washington. At present Martha seems to fill the centre of the stage.

Usually seedsmen carry what are termed two-year-old roots of asparagus which average no larger in size than yearlings. An excellent way to save time is to sow seeds under glass about Christmas, pot off singly into 2½s and later into 4s, gradually hardening off and planting out as soon as weather permits. There will be no loss from plants thus raised and they will grow five or more feet high the same season, and with me have proved far more satisfactory than either two or one-year-old dormant roots.

The amount of pleasure that there is in this world can never be measured. The philosophy of life is reciprocity and a man gets what he gives. Chauncey M. Depew.

Plants With Subterranean Stems

FLORUM AMATOR

WHAT is a plant stem? It is the axis of the plant on which all other organs of the plant are borne. Branches are secondary stems, that is stems growing out of the main stem. Stems at the very beginning produce roots. The stem is an ascending axis, except those subterranean stems which are in the form of a rhizome, and the root is the descending axis.

There are two general classes of stems, namely, above-ground and subterranean or underground stems. The pronounced characteristic of above-ground stems is that they bear leaves. Underground stems do not bear true leaves, but the rudiments of leaves or what answers to the leaves of above-ground stems.

Above-Ground Stems.—These stems are of several different forms, which are usually classified as follows: *Herbaceous* stems which die down to the ground each season after flowering; *suffrutescent*, which are slightly woody below, but herbaceous above; *fruticose*, woody and living through the years, but growing however not more than four times a man's height; *arborescent*, in appearance and manner of growth tree-like, and in size approaching a tree; *arborcous*, forming a proper tree trunk. These different forms of above-ground stems are found everywhere and may be readily observed, but subterranean or underground stems are not easily observed, and few consequently have any knowledge of these. It is of these, therefore, we purpose to speak.

Subterranean or Underground Stems.—"These," says the late Prof. Asa Gray in his excellent botany, "are very numerous and various, but they are commonly overlooked or else are confounded with roots. From their situation they are out of ordinary sight; but they will well repay examination, for the vegetation that is carried on underground is hardly less varied or important than that above ground."

Subterranean stems are of four different kinds, namely, the Rhizoma, Rhizome or Rootstock; the Tuber; the Corm, or solid bulb, and the true bulb.

Rhizomes, or Rootstocks.—The Rhizome or Rootstock is a creeping stem or branch growing partly or wholly beneath the soil. These are variously spoken of as scaly, running or creeping roots. The Spearmint, *Mentha veridis*, the Peppermint, *Mentha piperita*, the taste and fragrance of which are so refreshing, and also the hated "Couch Grass" or "Quick" Grass, *Agropyron repens*, are common and therefore well-known examples of plants with rhizomes. *Acorus calamus* Calamus, or Sweet Flag, is another example of a plant whose stem is a rhizome. The rhizome of this is sold by druggists under the commercial name, Calamus; it is edible and is often made more palatable by a coating of sugar and thus becomes a confection. The tender young spadices and the tender bases of the sword-like leaves also of *Acorus calamus* are edible. Still other examples of well-known plants with rhizomes are *Polygonatum biflorum* and *Polygonatum giganteum*, the smaller and the greater Solomon's Seal; *Smilicina racemosa*, False Spikenard; *Iris versicolor* and *Iris prismatica*, the Larger and the Slender Blue Flag, often called Iris and Fleur-de-Lis. These plants which have been mentioned as having rhizomes are all either indigenous or naturalized, but some cultivated Irises have rhizomes.

Tubers.—A tuber is a part of a rhizome (rootstock) more or less thickened and with buds (eyes) on its sides. As a matter of course there are all gradations between a

rootstock and a tuber. The common potato—*Solanum tuberosum*—and the Jerusalem Artichoke—*Helianthus tuberosus*—are well-known typical examples of the tuber. Other examples of the tuber are the Dahlia—*Dahlia variabilis*; the turnip—*Brassica* and the Ground-Nut or Wild Bean—*Apios tuberosa*. All of these tubers, which have been mentioned, are edible. The scalelike growth, which is seen at intervals on rhizomes and the eyes which are seen on both rhizomes and tubers correspond respectively to the leaves which are seen on the above-ground stems and the buds seen in the axils of these stems.

The Corm or Solid Bulb.—A corm is a thick and extremely short and fleshy underground stem, not unfrequently of greater breadth than height. From the upper end of the corm arise stalks and leaves and from the lower the roots descend or spread out. Among cultivated plants, the Crocus, Gladiolus and Cyclamen are well known examples of plants growing up from corms, and the Indian Turnip—*Ariscaema triphyllum*—among wild plants. The first two and the last are reproduced annually, the new corms forming on the sides and summit of the old, but the corms of the cyclamen enlarge and go on producing leaves and flowers through the years. A corm resembles a tuber in its habit of budding on its sides, that is from the axils of its leaves but these leaves are not scales as in the case of rhizomes and tubers but are the bases of the foliage leaves which cover the surface of the corm. The corm resembles the true bulb in having these sheathes or wide scales, but the solid part of the stem makes up most of the bulk which is not the case in the true bulb.

The Bulb.—A bulb is an underground stem whose solid centre is like a reduced corm, but whose major part is made up of thickened scales which are leaves or the bases of leaves and which cover the central corm-like part. In fact a bulb is a bud on an extremely short stem and surrounded with fleshy scales. In the bases of these thick, fleshy, overlapping scales is stored the food for the most part for the future growth of the central corm-like bud, surrounded by these scales but in the case of rhizomes, tubers, and corms the store of food for future use is in these subterranean stems. In lilies we see examples of bulbs with thick narrow scales.

In Hyacinths and Onions we have examples of coated or truncated bulbs, that is bulbs whose scales enwrap each other in concentric layers. The small bulbs which grow out of the large ones underground or in some cases above ground in the axils of the leaves are called bulblets. The bulblets which grow in the axils of the leaves of some kinds of Lilies or in the flower clusters of the Onions never grow into branches since they are buds with thickened scales, but when mature, drop to the ground and take root there and form new plants.

A proper and effective method of studying underground or subterranean stems is to procure a rhizome, for example, of an Iris, a tuber of a potato, a corm of a Cyclamen and a Gladiolus, a bulb of a Lily and a Hyacinth, and note first their forms; secondly their bud scales, and buds; thirdly their true roots, and from what point these roots spring, and from what point the new plant grows annually.

We will readily understand the importance of underground stems upon considering the fact that the majority of our most used edible vegetables and many of our beautiful flowering plants have stems which are wholly or partly subterranean.

Ornamental Flowering Trees and Shrubs

CAMILLO SCHNEIDER

In Gartenschoenheit, translated by F. B. MEYER

Japanese double flowering cherry, Kotugen Zakura.

March by the peaches and apricots in bright pink. Entire regions are famed for their fruit blossoms, in almost all large fertile river valleys and especially in the grape-cultivating regions on the Rhine and the Danube. In every place, where the cultivation of fruit is at all possible, the landscape is enriched.

But all that they offer is greatly augmented and refined by those peaches, plums, apples, pears and allied trees which we raise only for the sake of ornament, without thinking of their gifts of good tasting fruit. From all parts of the north temperate zone have these ornamental small trees come to accentuate and prolong the Spring

WHEN the blackthorn awakens from its Winter's rest we know that the fullness of Spring has come. Its branches, so mournfully dark in Winter, froth over, as it were, in white billows of blossoms, and at its feet in the green grass the violets exhale fragrance. Shortly thereafter, like white ribbons, the rows of cherry trees band the sunny landscape through which thrill the warblings of larks. In the fruit garden, the apples are already budding forth rosy-red and with the pear trees they close in May the blossoming period that had been ushered in during

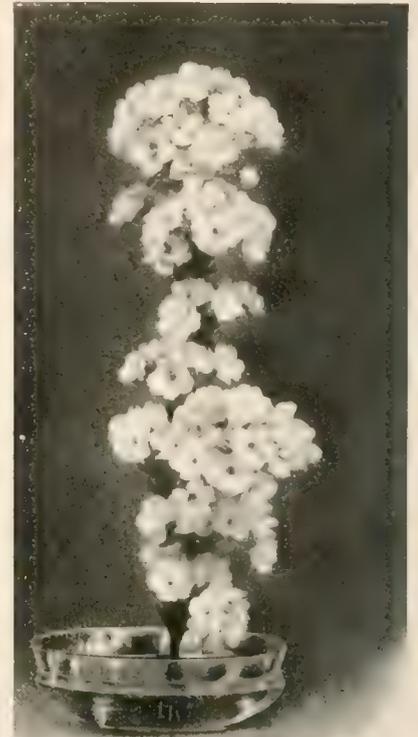

in our gardens. Japan and China have sent their ornamental cherries, and North America an abundance of splendidly flowering apples. From eastern Asia the most beautiful apricots, cherries, and pears have been obtained. But the Near East, too, has given us very handsome pears and apples. Their near relatives, the crab apples, *Aronia*, and the Rocksprays, *Amelanchier*, come for the most part from the United States. They are all counted among the most beautiful small trees and shrubs of Spring, which often in Summer and Autumn reward us doubly for the slight pains of our care with their splendid loads of fruit and their foliage gay in its coloring. The artistic plasticity of the petals, their small forms, the charming and rhythmic confusion of the stamens with the anthers, which in life are colored now purple, now gold, and all the niceties of the fruit capsules and styles, are generally overlooked when we stand admiringly before the wealth of the trees' blossoms.

Like the bee searching for nectar, our eyes must follow from blossom to blossom and gaze deep down into each of these miracles.

CHERRIES, PLUMS, AND THEIR RELATIVES (*Prunus*)

When in the last days of November, 1914, I was ascending from the hot valley of the Salween to Paszhoeh toward the Irrawaddi in the remote southwestern part of China, out from the darkness of the interwoven canopy of trees of the primitive sub-tropical forest there smilingly greeted me boughs of pink, announcing the bursting of Spring in this strange world. After long continued exertions my companions and I succeeded in bringing down

specimens of these blossoms. It was *Prunus ceragodes*, or Puddum, an ornamental cherry, which is spread throughout the Himalayan region and as far as western China. It meant an experience to me. It recalled all the vernal splendor of my native home—how often I had enjoyed it in the time of cherry blossoms and on the high bank of the Danube at Vienna or on the mountain road.

Japanese double flowering pyramid cherry, Amanogawa zakura; translated, Heaven's River or Milky Way.

Prunus ceragodes, Puddum, the Japanese cherry. The photographs produced hereunder through the courtesy of F. F. Wobler.

How a whole nation is raised to ecstasy is illustrated by the case of Japan. When the Spring Cherry, *Prunus subhirtella* blooms there in its characteristically weeping-form variety, *pendula*, a folk festival is observed. *Prunus yedoensis* or *paracerasus*, which is lacking in scarcely any park or temple garden, and at the height of whose blooming the Mikado ordains a holiday, rivals it for the people's favor. In time of flowering there follows upon this the numerous wild and cultivated forms of *P. serrulata* and of *P. Lannesiana*, both of which often pass among us incorrectly under the name *P. pseudocerasus*. To be sure I was not able to observe the Japanese ornamental cherries in my native home, but I learned thoroughly to know them and to prize them during the four Spring seasons I passed in the Arnold Arboretum at Boston. Here since 1890 the wild forms of *P. serrulata*, the variety *sachalinensis*, better known as *P. Sargentii* (Sargent's Cherry), has been successfully naturalized and every year its magnificent pink blossoms expand, along with the bronze-colored young foliage, to the delight of thousands who stream into the Arboretum at cherry blossom time. The following garden forms of *P. serrulata*, which belong to the variety *sachalinensis*, are quite wonderful: *alba rosea* (Shiro-fugen) pink buds, open flowers with two carpels, shaped like leaves, in the center; Fugenzo (James Veitch or *Veitchiana* of the gardens) like the preceding but rose-white blossoms; Hisakura Kirin, very large, compactly double, pink, late blooming; Seckiyama, bright pink, large, double and, according to E. H. Wilson, who has studied these forms in detail, perhaps the most lovely double ornamental cherry. To *P. Lannesiana* belong, according to Mr. Wilson, the following magnificent forms: Sumizone, single, white with pink-blush, fragrant, very large; Fukwokuju, first light pink, then white, double; Hatazakura, white with pink, semi-double, somewhat like an apple; Jonior, pure white, rather loose, strongly fragrant; Oyon, semi-double light pink; Ojochin, semi-double, light pink, very large. Not without mention should remain *P. Sieboldii*, which in the gardens passes as *P. pseudocerasus* var. *Sieboldii* or var. *Wateri*, as well as under its natal name, Naden. The blossoms are pink, quite double

or semi-double, the last being the case with the kind called Yohiki. With this, of course, the number of Japanese ornamental cherries is not exhausted. Their history is highly interesting and is treated in a discourse written in German by M. Miyoshi, which appeared in 1916 in a Japanese scientific journal at the same time that Mr. Wilson published his work on Japanese cherries in the Arnold Arboretum. According to Miyoshi the kind Fugenzo has been known in cultivation for more than four hundred years while a work of the year 1681 already takes

Japanese weeping cherries, pink, single, *Shidare-Higan-Zakura*, and *C. subhirtella pendula*

account of forty sorts, of which twenty-one have been kept till the present time.

The group of peaches and apricots at this time I can only briefly touch upon. Among apricots should be noticed as a lovely Spring bloomer, *P. sibirica*, the Siberian form of *Armeniaca*, whose precocious splendor, to be sure, only too often is severely damaged by late frost. The same is true in the case of the Manchurian form, *P. Mandshurica*. In the Vienna Botanical Garden there stood until about a decade ago a lovely tree of the Siberian apricot, which, according to my observation through a number of years, used to bloom very nicely in March. I sent some seed of it to the Arnold Arboretum and was able in 1916 and 1917 to see plants,

GUI-TOI
Tears of the Dragon

Graceful, but slow growing, *Malus Halliana* or *Parkmanii*.

raised from the seed, in bloom, which, however, were not as effective and rich as in Vienna. *P. Sibirica* passes at times as *P. Mume*, also the genuine Japanese apricot. It resembles our *Armeniaca* very much in foliage but has rougher pits from which the flesh does not separate. Grand too is the cherry almond, *P. persicoides*, whose leaves remind one more of the almond *P. communis* while the fruits resemble more those of the peach, *P. persica*. A very good early almond which I was able to study for years in Vienna is *P. Fenzliana*, disseminated in the Caucasus and the Amato. It is lower and more spreading than *P. communis* and endures right well in regions of warm summers. The ripening of the wood and of the blossom buds in the case of all these early bloomers is very important. We must always call attention to the splendid double forms of our peaches. Kinds like *dianthiflora* and Clara Mayer have in their color, tones which lighten intensely, a quite extraordinary effect in the garden.

The plums are no less deserving of special attention. So above all are the American cherry plums like *P. americana*, *P. nigra*, *P. hortulana* and its related forms. A peculiar and very rich blooming type from China and the Himalayas is *P. salicina* (*P. triflora*). The cherry plum, *P. cerasifera*, also must always be thought of, especially in the exceedingly decorative purple-leaved form, var. *Pissardi*, to which are closely related the forms *Hessci*, *Purpusii* and *Blireana* which in the deep variable tones of the young foliage, combined with the pink of the blossoms, mutually strive to surpass one another. The last named is distinguished by its semi-double blossoms, while they are slightly more filled out in the form *Moseri*. Even with this the chapter of early blooming prunuses is far from being completed.

THE APPLE (*Malus*) AND THE PEAR (*Pyrus*)

The East Asiatic and North American ornamental apples are certainly not inferior to the Japanese cherries in beauty of blossom. They particularly surpass them in duration of bloom and besides, bestow upon us in the Autumn a wealth of variably formed and variably colored fruits, which often last throughout the Winter. Since the blossoming of apples begins later than that of cherries they do not so often suffer from late frost. In reference to the charms of their habits the ornamental apples make almost more of an appeal than do the ornamental cherries. On all these grounds they deserve our respect in the highest degree and they should not be lacking in any garden.

One of the most beautiful ornamental apples is *M. baccata*, the area of which extends from eastern Asia through China up to the Himalayas and accordingly appears in various wild forms. It is known as the Siberian apple and its fruit is esteemed in making jelly. In its form *mandshurica*, *M. baccata* blooms as the first of all ornamental apples and almost at the same time the blossoms of a hybrid form open, long known in cultivation under the name of *M. cerasifera*, which now must take the new name *M. robusta*. It represents a cross between *baccata* and *prunifolia*. *M. Halliana Parkmanii* is the best known Chinese sort, the type of which, to be sure, has not yet been found in a wild state in China. On the other hand the variety *rinki*, known in our gardens as *M. Ringo*, has been met with in wild state in central and western China. It has been cultivated by the Chinese for centuries and is recognized as the most important apple of eastern Asia. In my opinion the most beautiful Chinese ornamental apple is unquestionably *M. Halliana* in its double form *Parkmanii*. I have so often admired its wonderful rose-red pendant blossoms in the Arnold Arboretum that I should like to see it

again in every garden in our country. The double form in Japanese gardens goes under the name Kaido. A very noteworthy hybrid with *baccata*, which originated in Germany, is *M. Hartwegii*. Striking is the newer Chinese, *M. theifera*, which owes its name to the fact that Chinese country people make the so-called red tea from its leaves. This sort in the bud state is rose-red, later nearly white; its growth is spare and the bushes develop a large number of thorn-like twigs which bear the flower clusters.

But China is rich in quite various types of apples. There are, to mention only such as have already been tried in cultivation in America and England, and in part have been introduced into our own country, also, *M. kansuensis* and *M. transitoria*, which belong to a group of sorts that are related to the American *M. fusca*. Another type I have myself observed wild in Yunnan: *M. yunnanensis*. This sort reminds one in its foliage of *M. Tschonoskii* which came to us from Japan a rather long time ago. It leads to a certain extent to an ever-green type *Docynia* which is distributed in the Himalayas and western China and whose magnificence of bloom I learned to know on my travels in Yunnan; it is distinct from genuine maluses. These brief references may pass for an indication of how rich is the Chinese plant world in peculiar forms, deserving of cultivation.

From Japan are to be mentioned for the smaller gardens, *M. Sargentii* and *M. Sieboldi* var. *calocarpa*, as *M. Zuni* also. *M. Arnoldiana*, belonging in the form cycle to *M. floribunda* is worthy of the same note. *M. ioensis plena*, the double form of the prairie apple, from North America, is unsurpassed. Its large, fragrant and compact flowers remind one of small roses. Very decorative is one from the Caucasus, related to our wild apple, *M. Niedzwetzkyana*, which on account of its magnificent red colored foliage and blossoms truly deserve a better name. Its large purple apples are also striking, though its habit unfortunately is very sparse and unlovely, so that its decorative value is impaired.

In spite of the fact that apples and pears are in every way quite distinct they are often still classed under the name *Pyrus*. Real pears, however, are very easily distinguished from apples in leaf, blossom, and fruit. They are in general not as ornamental as the apple but they also possess their charms in the blooming season. Even the common wild pear, *Pyrus communis*, attracts our gaze when blooming. From it for the most part are derived our cultivated forms, in the origin of which, however, the snow pear, *P. nivalis*, has had a part. This is still found occasionally wild in old country gardens. Old trees of it have a very picturesque appearance and with their large white blossoms are charming. The west Asiatic willow-leaved pear, *P. salicifolia*, like the olive-leaved pear, *P. clavigrifolia* also from the Caucasus and southern Russia, is very charming in spite of its rather small blossoms. From China and Japan we possess now a whole series which, as stocks and even on account of their fruits, play a role. Even though the fruits of the Chinese kinds by no means have the melting juiciness of our cultivated pears, but rather, in spite of their often considerable size, are quite stony, one learns to prize them for their keeping qualities, for when stewed they make an excellent preserve. (Continued in the September number.)

The flowering cherry is effective in landscape compositions. Observe how profuse is the flowering of the tree, illustrated on the front cover, in front of the little building and of the one at the rear. The cover illustration, and the other illustrations of ornamental flowering shrubs are produced, in connection with this article, through the courtesy of A. E. Mohbert.

The Iris Among the Ancients

IN the remote time of Greek mythology the Iris was a gracious goddess, messenger of the gods, who by spreading out her scarf produced the rainbow. The ancient Greeks, struck by the diversity of colors in the perianth of the flowers of the plant which forms the subject of this article, gave to it the name of the charming goddess who personified the rainbow.

The Greek physician Dioscorides, of the first century of the Christian era, declares moreover that the word Iris signifies "rainbow"; the plant bearing this name, he adds, owes it to the varied colors of its petals.

At that period the Greeks and the Romans employed the dried rhizomes of the Iris in perfumery and in medicine. They made use of it to combat coughs and colics, against the bites of serpents, as a purgative, etc. Pliny and Dioscorides point out that the rhizomes most esteemed came from Illyria (*I. germanica*); in the second rank were placed those from Macedonia (*I. florentina*), and finally, in the last place, those from Lybia. Macedonia and Corinth were then celebrated for their perfumed unguents. According to Pliny the better oil of Iris came from Pamphilia; that from Cilicia also was very highly esteemed. The German botanist, Sprengel, sees, in the Iris of Dioscorides, the species *germanica* and *florentina*.

If in the first century the rhizomes of the Iris were imported into Italy the plant was already known there and had a place in the gardens. Pliny states that it did not enter into the making of garlands, probably because of the fragility of the petals. He describes minutely the ceremonial pulling up of the rhizomes, which were lifted up toward the sky immediately they were taken from the earth.

On the contrary the Egyptians, in the Greco-Roman period, who cultivated the *Iris sibirica*, used it to make garlands.

What were the Irises cultivated by the Greeks and the Romans? They cultivated, beyond doubt, the *I. germanica*, native to central Europe, which grows in abundance in a wild state in Dalmatia (ancient Illyria). It is evidently this species, of which the colors recall the rainbow, that brought to the genus its name.

According to Fluckiger and Hanbury *I. florentina* and *pallida* (from the south-eastern parts of Europe) must have been introduced into Italy in the Middle Ages. The Italian agriculturist Crescenzi (13th century) actually treated of the *white* Iris and of the *purple*, and indicates the manner of preserving the rhizomes. His contemporary, the celebrated poet, Dante, author of the *Divine Comedy*, reports that upon the ancient arms of the city of Florence was a representation of a *white* Iris upon a red escutcheon, which was, after the civil wars, changed into red Iris upon a white escutcheon. The culture of the *I. florentina* spread rapidly to such an extent that Valerius Cordus complained, at the end of the sixteenth century, that the Illyrian drug had been replaced by that from Florence. According to the statement of Mattioli the plant must have been naturalized in Tuscany in the middle of the sixteenth century. Clusius claims that it was rare in the gardens of the other countries.

In the twelfth century, in Spain, the Arabian agriculturist Ibn-al-Awam described the culture of the *Iris* (Little Violet-colored Lily), which multiplies from the roots in May; the translator wrote in a note that this Iris, of small stature, was probably the *I. pumila*. The Arabian physician Ibn-el-Beithar (13th Century) says that the *Irissa* is the violet-colored Lily, and he points out its medicinal properties.

In France the culture of the Iris goes back certainly to a remote period; the beauty and the oddness of its flowers, the perfume of its dried rhizomes, employed since time immemorial in domestic economy (lixiviation, heraldry) must have caused it to be admitted into gardens. In the eighteenth century, under the name of *Gladiolus* (in 1600) Olivier of Serres still wrote *Gladiolus* or *Iris*. The emperor Charlemagne enjoined the cultivation of the *Iris* upon his attendants.

The flower is found represented upon the scroll work of monuments of the Roman period and of the end of the Gothic period. The flower of "Lys" figured upon the coats of arms of the kings of France, from the time of Louis VII in 1180 (it had been adopted by other royal houses of Europe also and by a great number of families belonging to the French nobility), does not resemble a fleur-de-lis. Modern authors see rather, in the golden Lily of coats of arms, the yellow flower of the *Iris pseudacorus*.

It is then not rash to affirm that by the Middle Ages the culture of the *Iris* had already been widely spread in France. In the sixteenth century the species known were sufficiently numerous. By consulting the works of botanists of the time, up to G. Bauhin (*Pinax* 1623), we have found, described or figured, the following Irises:

I.—Iris rhizomatous:

- (a) Apogon: *I. fatidissima* L., *I. pseudacorus* L.; *I. graminea* L.; *I. sibirica* L.; *I. spuria* L.
- (b) Oncocyclus: *I. Susiana* L.
- (c) Pogoniris: L.; *I. aphylla* L.; *I. germanica* L.; *I. florentina* L.; *I. pallida* Lam.; *I. pumila* L.; *I. squalens* L.; *I. sambucina* L.; *I. variegata* L.

II.—Iris bulbous: *I. alata* Poir; *I. Xiphium* L.; *I. xiphoides*, Ehr.; *I. Sisyrinchium* L.; *I. juncea* L.

III.—Iris tuberous: *I. tuberosa* L.

This is the total of twenty species. Thus, as witness the works of Clusius and of G. Bauhin, where Lamark found described several varieties of *I. germanica* and of *pumila*, the cultivation of these two species must be ancient. The Mourning Iris or *I. susiana*, so curious because of its form and its sombre coloring, native to Persia, of which we reproduce the figure according to Clusius, was sent from Constantinople to Vienna in 1573 to this botanist. The Iris from Persia (*I. persica* L.), bulbous, is cited in 1629 by Parkinson.

It is from the end of the sixteenth or from the beginning of the seventeenth century that the culture of bulbous irises has been developed in Holland. Clusius, whom Olivier of Serres (the Father of French Agriculture) sur-named in 1600, the Father of Flowers, must have introduced and propagated numerous species when he was in Leyden. The attention of Dutch, English and Belgian horticulturists was directed principally to the bulbous species (*I. xiphium* and *I. xiphoides*) of which they obtained, by sowing, numerous varieties. De Grace announced (Bon Jardinier, 1802) that in the eighteenth century the Dutch were selling, by names and colors, varieties of *I. xiphium*.

In France, in the seventeenth and eighteenth centuries, were cultivated, in the gardens, rhizomatous irises (*I. germanica*, *I. pumila*, *I. florentina*, *I. Susiana*, etc.) and bulbous irises (*I. xiphium*, under the name of Spanish Iris, *I. xiphoides*, under the name of English Iris and the Persian Iris). Irises with rhizomes were multiplied from seed or, more often, by cutting up the rhizomes. A

The Rock Garden

ARTHUR SMITH

WHEN people begin to realize the results which are to be obtained by gardening exclusively with hardy plants, the ever-changing variety of beautiful effects produced for the greater part of the year, and the boundless possibilities connected with the system compared with that of using tender bedding plants, they desire to bring into their gardens some of the many enchanting subjects which find a congenial home among rocks, especially those inhabiting alpine situations. Hence a rockery is made with the idea of accommodating them.

A rockery may cover only a few square yards, or one can form a rock garden of any extent in which may be created all kinds of situations, variations in soil, aspect, etc., suited to the needs of plants growing in mountainous districts, which needs distinctly differ in different species, whether from arid Arizona or from mountains above the tree line close to perpetual snow.

Whatever the extent of rock-work we propose to undertake, the underlying principles of construction are the same. That these principles have not always been realized accounts perhaps for the fact that there are few matters connected with horticulture wherein there have been more failures and ridiculous results than in the formation of rockeries.

The use of rocks in connection with growing plants is, as far as possible, to create conditions similar to their native habitat, and also to counteract to some extent the adverse conditions brought about by a distinct change in that habitat.

One of the most important points connected with the naturalization of plants is to produce as far as possible the environment in which the plants have been in the habit of living. The fact that a plant has been growing under certain conditions for thousands of years and is found in no other, is evidence that those conditions are the best for its constitution. Therefore if we wish to grow the many beautiful subjects which are to be found upon the mountains we must give them a home which reproduces to the greatest possible extent that from which they have been removed, and at the same time protect them from the adverse effects which may arise from the differences in their new environment.

The mistake is often made in thinking that these plants grow upon rocks. It is true that a mere passing glance might lead one to suppose such to be the case, but if closely examined it will be found that their roots go down deeply into the fissures of the rocks, and in cases where these fissures have been opened up roots have been traced down many feet and are thus safe from cold and drought.

This prevailing idea that rock plants grow upon rocks and that therefore they require little or no soil no doubt accounts for the method frequently employed in making rockeries, which is to dump a few loads of stones upon the top of hard ground, form them into a sort of pyramid, poke a few spoonful of earth between the stones and ram in the plant with a stick. It is true there are one or two species which will more or less survive this treatment, such as *Sedum acre*, and *Semprevivum tectorum*, but one does not go to the trouble and expense of constructing rockeries merely for subjects like these which will grow in any poor, droughty situation, although they may rightfully have a place there.

The first point to be considered is the site. This should not be near trees because their roots will inevitably find their way into the soil of the rock garden and rob the

plants of food and water; the drip from trees is also very detrimental. The situation should be an open one away from tall buildings.

The realization of the advantages of having the rock garden in an open situation has perhaps led some people to construct them on a lawn, fully exposed and therefore part of the landscape. However ideal may have been the construction and planting of a rock garden, having a rockery or a rock garden standing out upon a lawn is a fundamental mistake, inasmuch as a condition is created which cannot possibly harmonize with any other feature of the garden and a discordant note is thereby established.

Of course, one has to make the best of the conditions which they possess, but if possible a garden of this kind should be so enclosed by natural planting that from the outside it will harmonize with, and appear part of, the general landscape scheme—provided the latter is upon naturalistic lines—and it is possible so to arrange matters that it will appear to be nothing but a somewhat more pronounced promontory of a boundary planting, and the rock garden itself will not be seen until one is actually in it.

With the latter idea in mind—although it is only one of many possibilities—such promontory may take an irregular pear shape in outline with the narrowest portion in connection with the other planting. This narrow connecting neck should gradually widen out to any width, and extend to any length, the room at disposal or the desires of the owner may require.

As soon as the neck widens out the formation of banks should commence, bifurcating to any width desired and meeting again at the other end. The banks should be irregular, obtuse slopes, but the out line of the exterior can be smoother than the interior.

The planting on the outside of the banks should be of a shrubbery, evergreen nature, conforming to that with which it is connected. The species used may be, however, of the dwarfer kinds, especially on the higher parts of the bank, so as to avoid any sudden elevation of the sky line, so that from the outside it should have no conspicuous difference from the other planting in its vicinity. The selection and placing of the material used should be considered from the point of view of the height reached by the different species, and upon the bank itself nothing of a coarse growing nature with far reaching roots is advisable. If a border of herbaceous perennials is in front of the planting to which this is connected such border should continue. Properly masked entrances may be made at each end, or only one entrance may be provided for.

The interior will present a more or less irregular shaped oval surface surrounded by the banks. Water effect can be provided for by means of having it issue from between rocks in the form of a spring at one end, continued along the center in the form of a winding rivulet, or enlarging into a pool, and disappearing into a drain at the other end.

As regards soil, most plants will do well in a sweet, fibrous loam, and for rock plants, especially alpiners, one composed of one part fibrous loam, one part leaf mold and one part sharp grit is advisable. The grit should not be round smooth pebbles but riddled broken stone and should vary from the size of cabbage seed to that of pigeon eggs.

As regards the kind of rock to use, that natural to the district and nearest at hand—provided it has no objection-

able features—is the best on economical grounds. Rock which crumbles when exposed to the weather should not be used, nor should very rounded, smooth rocks, as the latter are difficult to make and keep firm. The use of pieces of concrete, clinkers, brick, broken columns, or any kind of artificial stone should not be thought of.

A more or less soft stone is not suitable however well it may look at first, because frost will cause it to break into chips and even crumble into powder. It is necessary to be particularly careful with limestone on this account. No stone varies more than this; some kinds go in a year or two, while others are quite durable. If it has a dull, powdery appearance it should be rejected, if bright and sparkling it may be used, but even the hardest limestone had better be left out of gardens near towns, especially in smoky manufacturing districts, as it is readily affected by sulphuric and other acids.

In some parts limestone is abundant and there is a natural temptation to use it if quarried nearby, as the cost is low. One great thing in its favor is that the majority of rock plants like it and in this case their roots cling to it with an intimacy which suggests active favors. Alpines are more markedly lime lovers than others, but there are some, however, which dislike it. Sandstone is good, suits everything, has an excellent appearance, and is durable.

While places are to be found for rocks of all sizes and shapes, they should generally be somewhat rectangular and longer than wide, so that they can be bedded securely with little trouble, and stones of more or less flatness fit in more readily with the scheme of work than those tending to roundness. It is not suggested that the paving-stone form is ideal, and dressed stone would look too stiff.

When arranging the rocks they should be placed in as natural a manner as possible. Start from the bottom and build upwards, fixing the rocks firmly so that one can stand upon them when planting, weeding, etc. They should slant so that the exposed portion is at a higher elevation than that which is buried, this will cause the rain to run back to the roots instead of dripping over and spoiling the plants below. It is very important to take care and fill up the soil well behind each rock as well as under it as it is laid in position. Make all quite firm as the work proceeds, for if this is not done the result will be that after heavy storms either the rocks or soil, or both, will sink, and by so doing cause a great deal of mischief. Placing the soil in position and then putting the rocks more or less on the top is the least desirable method of building a rockery.

There is nothing in mountainous districts where alpine conditions prevail so likely to mislead as the arrangement, or want of arrangement, of the rocks. Some of the ugliest and most desolate rock gardens are the result of attempts to imitate the savage chaos of alpine boulders, which is supposed to be favorable to plant life because some alpines are found to be thriving among them at elevations of ten thousand or more feet. Now we can in our gardens provide an absurd and insignificant imitation of this chaos, but we cannot provide the elevation with the pure mountain air, the sustained Winter frost with its constant snow mantle, and the continuous Summer moisture. The strewing of boulders at random upon the surface will enable a few stone crops to flourish among them, but most other plants worth while going to any trouble for will take the first opportunity of dying, and a chaos in a garden devoid of vegetation is scarcely less ugly than a rubbish heap.

In studying the rock work of Nature in its relationship to plants we should know the actual function which rocks should perform in a garden, and particularly we should bear in mind the frequently ignored point that in making

a rock garden we are not constructing a garden for the purpose of exhibiting rocks, but for the purpose of growing rare and beautiful plants. If this is kept in mind one can gain many valuable hints from alpine districts. The first of these is that all rocks should be so placed that the roots of plants near will be able to run under them and so get protection from drought in Summer and cold and wet in Winter. Some ambitious rock gardens may be seen with the rocks driven down perpendicularly into the earth, in which position they are practically useless. Those who have been in alpine districts will have noticed that the fine specimens of plants are to be found—often in conditions not otherwise favorable—at the edge of a great boulder which slants into the ground, so that the roots can run under it and get coolness and shelter as far as they are likely to penetrate, which is usually many feet; and it is in the slanting fissures of rocks that many of the more difficult plants grow best and most abundantly. Therefore we should never place a rock without thinking of the plant which is to profit by it, nor should we consider rocks apart from roots, for the sole function of rocks in a rock garden is to protect roots and not merely to look rugged and picturesque; although the gaining of picturesqueness need not be overlooked.

According to the size of the rock garden, ridges and bays may be formed, and the larger the area available, the deeper the bays; and the deeper the bays the longer the ridges. Looking into a bay gives a pleasing illusion of distance, also this method gives more space for plants upon a given area of flat surface. Further, this arrangement affords more varied aspects in relationship to the sun, and therefore provides positions suitable to the varying likes and dislikes of plants as to shade or the reverse.

Arranging the rocks so as to form pockets is advantageous because we can then make such additions to the soil as will suit the plants placed in any particular pocket. For instance, some like plenty of lime, which can be given them in their own compartment; others are to be found which like a soil composed of three parts leaf mold or peat, and so on. When lime is added it should be in the form of broken lime mortar, or lime rock; ground, burnt, or slaked lime should never be used for this purpose.

When placing the plants in their positions one must have a clear idea of their characters, not only as to their soil requirements, but if they like or dislike full sun; if they are vigorous and comparatively rampant or otherwise. Disregard of the latter point has frequently caused dense, low-growing little plants to be soon killed by those of a taller and spreading character. It is best to give the most vigorous species a section by themselves, or plant them at the lower levels and the weaker ones above. If there is only room for a small rockery it would be preferable to confine the selection to the smaller, choicer kinds and leave the more rampant ones out altogether.

After planting, the plants should be surrounded by small stones or broken rock, this keeps the soil cool and also minimizes the adverse effects of wet in the Winter.

Growing alpines require perhaps even more of that patience which one must have in all horticultural matters. Some species may take several years to become established, so we must not throw a plant out because it does not thrive immediately, for so long as there is life there is hope.

While there are some species of alpines which have defied all attempts at growing them in captivity, the majority of them can be successfully made to thrive. The greatest trouble is with the wet in Winter. In their native homes the seasons create two distinct conditions: a Summer of about three months and a dormant period for the remainder of the year, during which they are continuously

covered with a mantle of dry snow. Alpines are never killed by cold Winters but by wet ones. The ill effects of wet in Winter may be prevented by covering them with sheets of glass. Some have erected glass houses over their more delicate alpines, so constructed that they can be taken apart and stored away during the Summer.

One of the secrets of success with many species is to give them an annual top-dressing or "earthing up" of gritty compost. Some of them are constantly being subjected to the same kind of treatment by Nature, for in Spring the melting snow carries down earth, grit and stones on to them. Species like *Daphne*, *Alyssum saxatile* and *Iberis*, to mention well known plants—which are true alpines, although not generally known as such, especially require this treatment. It is within the experience of most people that these plants become in a few years "leggy," if they do not actually die out. This is caused by their habit of growing out of the soil, which habit they have no doubt acquired in consequence of having been accustomed to the natural top-dressing given them by the melting of their own mountain snows. They have learned that if they did not rise up they would be buried under the annual deposit, and they have not yet been long enough in cultivation to learn to adapt themselves to the change in environment.

Perhaps the most interesting and instructive method of working up a collection of alpines is to go to the mountains and collect them, as there would be in this course the distinct advantage of seeing them in their natural habitat. Seed should be collected as well, for there are many species which do not take kindly to removal. One important point which will be realized by anyone taking a mountain trip is that various distinct situations exist where some plants do better than they do in others, and also that some species grow under certain conditions and in no others. For these reasons, in forming a rock garden, it should be so laid out as to present varying situations, and if water be available it will be a distinct advantage to cause it to emerge from a position on a bank in the form of a natural spring and trickle over the rocks so as to create boggy places like those which frequently exist in the mountains and by this means the range of plants which may be successfully grown is greatly extended.

It must be borne in mind that the word "alpine" is not confined to plants native of "The Alps," as alpine conditions exist all over the world, from mountains which arise out of tropical plains, on towards regions of perpetual ice; before the latter is reached alpine plants will be found at the sea level. From New England to the Pacific coast this country has many alpine situations and the Mt. Rainier district is especially rich in alpine flora, and most of the American alpines are untouched, and for the most part unknown, by American gardeners. A number of American rock plants have been used for years by British rock gardeners, and seeds of these and other species can be obtained from specialists in that country.

While, as before stated, a rock garden may be caused to afford conditions which distinctly differ so that the garden can accommodate a wide range of species, we must not think of planting in it low and herbaceous subjects which have their proper place in a border of herbaceous perennials, as plants of the latter kind are not appropriate to a rock garden. The fact that an alpine plant is sometimes grown in a herbaceous border, must not blind us to another fact that the herbaceous border and the rockery represent two distinct phases of hardy flower gardening and attempts to combine the two always end in failure.

Besides a rock garden proper, there are many other situations which can be beautified by the use of true rock plants, among which may be mentioned, steps, uncemented

walls, embankments which are faced with loose stone, and such like positions. Where possible it is always well to have a good thickness of suitable soil at the back of stones in the above situations, and it is better to have the placing of the stones and of the plants go on simultaneously.

(Continued in the September number.)

IRIS AMONG THE ANCIENTS

(Continued from Page 229)

number of varieties must have been produced in cultivation.

If Holland and England have played a preponderant role in perfecting bulbous Irises French horticulture can claim the honor of having been the first to effect upon a large scale the creation of numerous and magnificent varieties of "Garden Irises."

In 1922 De Bure, who died in 1842, inaugurated the era of raising rhizomatous Irises from seed. He made his experiments at that time out in the country and in his garden at 13 Hautefeuille St., Paris. He obtained a beautiful collection of new varieties of which one, more remarkable than the others and much appreciated at the time, was called *Iris buriensis*.

Toward 1839 Jacques, of Neuilly (Seine), also sowed seed of the Iris and possessed an important collection of new varieties of his originating.

From 1836 Lemon the Younger, a professional horticulturist, 3 Denoyez St., Belleville, commenced to make sowings, continued them during following years and had, in 1839, 150 varieties, of which 100 were choice.

Then Pele, horticulturist, Paris, after he had united the most beautiful known varieties, effected in his turn some sowings and augmented the number of beautiful varieties to which preceding horticulturists had accustomed the public.

On the other hand Loiseleur-Deslongchamps, in his garden, by consequence of natural sowings of the seed of *I. squalens* and *variegata*, had obtained some beautiful varieties.

The names of De Bure, Jacques, Lemon and Pele ought to be remembered; they are the first great French growers of Iris from seed.

To obtain new varieties the horticulturists of the first part of the nineteenth century sowed seed from species that produced it with sufficient regularity. Their "Garden Irises" descended from *I. variegata* (See the illustration), *plicata*, *sambucina*, *squalens*, *svertii*, *pallida*, *flavescens*, *urida*, etc., all of the *pogoniris* section or the Bearded Iris. It is in error that toward 1837 or 1838 there was attributed a part to *I. germanica* in the production of new varieties. This species fruits rarely and in 1840 Lemon declared that he had not been able to obtain seed from it since he had been handling Iris seed. Isole, *I. germanica*, almost never gives seed; it has since been observed to form seed when it is associated with other species.

The numerous varieties obtained, remarkable for the delicacy of their shades and the richness of their coloring, have come from the seed of different species; moreover, so far as we have been able to judge, it seems that the first men who sowed the seed of the Iris did not give themselves to hybridizing, at least not in the greater part of their career.—Tr. from *Revue Horticole* by F. B. M.

I would rather attempt and fail a thousand times at something in which I had put my heart than to win with a single bound at something that held only some temporary thrill. Big, bold things! They are the only inspirers. In them may we delve and sweat and thrive, for though we may temporarily fail—we can never lose.
—George Matthew Adams.

Gardening in South Carolina

ANDREW ANDERSEN

When I was called upon to go to South Carolina to plan and plant an estate for the owner of a cotton mill town, little did I know of what was ahead of me in the way of climatic conditions and the labor situation in general. It was my first attempt in the South and amusing indeed is it—to say the least—to see the native negro go about his work. Slow and lazy as he is, he, of course,

A view of the rose garden on the Mebane estate, Great Falls, S. C.

knows more or less how to grow cotton, or can at least plow and apply the fertilizer to the fields. Most of the plowing I have seen, however, consists mainly of scraping the surface which is not exactly one of the best methods for successful farming. Cotton is the watchword, though one may see a good stand of corn or wheat occasionally. As yet I have not seen a good pasture.

I want particularly to tell you a little about the gardening end of it:

For certain reasons it was not practicable to import white experienced garden laborers, so the very first thing to do was to get a gang of Africans interested in the profession of gardening, and this training was the most difficult task I have ever been up against. Such raw material has been a steady handicap to proper plantings and the

The swimming pool showing the planting of native cedars.

preparations for such. December, January and February form the planting season, but occasional hot and dry spells through this period even necessitate great care and a well established planting before hot weather sets in, is a necessity to success; otherwise failure is sure to come. Hot Summer weather begins in May and continues into November.

After all, roses are doing splendidly, better than any-

thing else. The rose bug is an unknown pest here. I am growing hybrid teas and a few teas only, and such climbers as Marechal Niel, Gloire de Dijon, the Van Flet, Tausendschon, American Beauty, and Silver Moon, the greatest of them all. A snapshot of a rose garden planted in November and taken the following year in May is shown on this page.

Flowering shrubs such as magnolias, lilacs, spireas, weigelas, deutzias, and a score of others are practically flowering at the same time, but doing fine as they flower in March or April. Ahead of these come the forsythias, bush honeysuckles, azaleas, and not uncommon is it to see these poor harbingers of Spring being destroyed by a February sleet storm, magnolias included.

It is not unusual to see wonderful specimen gardenias, and they, by the way, flower twice a year. *Enonymus* jap, with its beautiful foliage and red berries is another wonderful lawn specimen in this locality. The orlanders are attractive for the same purpose and spread immensely in a few years time, and last but not least I want to mention the crape myrtle, another decoration for the lawn and just coming in when flowering shrubs are scarce.

Shade trees such as Norway maple, European linden,

A specimen tree for Southern lawns, *Ligustrum nepalense*.

elm and plane are quite at home, and right here I want to call attention to one beautiful native tree, the willow oak, an evergreen oak so to say, with foliage resembling the laurel willow, slightly narrower, a very graceful and desirable tree for all purposes (*Quercus phellos*).

The woods are full of red cedars, hollies (large leaf) and the most beautiful dogwood I have ever seen. With this material we have made some very beautiful plantings with an occasional sprinkling of a corkbark elm and red oak.

The long leaf pine is a wonderful looking tree, but does not want to be moved, at least this is my experience with this variety of pine, and I am sorry to say that I have failed utterly!

For the plantings at the main entrances and for lawn specimens and driveways we bought nursery stock from the North. The plantings at the swimming pool are native cedars. The large tree or bush in circle of one of the pictures is a *Ligustrum nepalense*, a beautiful large leaved evergreen with its large blue berries in big clusters remaining on the tree all winter, a good specimen tree for a Southern lawn.

The spruces, particularly so, *pungens* and *pungens glauca Kosteriana*, are looking very well and making fine
(Continued on page 237)

The Nasturtium

BERTHA BERBERT HAMMOND

The nasturtium or *Tropæolum*, an introduction from South America, has long been a favorite in the gardens of our country, where it is cultivated as an ornament and also for its edible qualities. (The young tender leaves of *Tropæolum majus*, better known as Indian Cress, are highly esteemed for use in salads; the unripe seeds are used in relishes.)

As an ornamental garden plant the nasturtium holds a high rank. Even when not in bloom, the odd-shaped leaves, the coloring which according to variety may be light or dark green, purplish green or variegated, make it quite decorative, and when covered with profusion of exquisitely formed flowers, which in variety of coloring run the gamut in all shades from creamy white through the yellow, crimson to purplish-violet shades, then these plants form a dense mass of harmonizing color that cannot be excelled. Indeed, the flowers of the nasturtium are so wonderfully and strikingly colored, striped, spotted, mottled and variegated in such a charming medley that one is ready to think like Bessie Johnson-Bellman who says:

When Flora had finished her labors
And all the flowers were made
She still had left on her palette
Many a brilliant shade.

So she gathered them all together
And added a drop of dew
And a breeze from sunny spice-land
And then the Nasturtium grew.

The twining sorts of nasturtiums classed among the best of annual climbers with their luxuriant growth are well adapted for covering fences, trellises or unsightly objects. For trailing over rough ground they are especially fine, as a planting of rows of entwining vines will soon produce wonderfully attractive carpeting. With us some long rows on a hillside where other flowers have seemed ill at ease, in a short time transformed the slope into an attractive spot and yielded besides the gorgeous display of bloom, plenty of tender cress and quantities of seeds for culinary purposes. This Spring, seeds tucked away into earthy beds in the crevices in an old stone wall, and here and there along the over-hanging borders of a brooklet and in other odd and unexpected places furnished a most interesting planting full of happy surprises. As a trailing vine in window boxes, hanging baskets or in ornamental lawn vases the showy, graceful, twining nasturtiums are excellent, and the improved drainage secured by the raised position, tends to increase the number of flowers and adds to the grace of the long hanging branches. This variety is also well adapted for use in covering rockeries, tree stumps or other similar objects with a trailing jewelled mantle, that cannot fail to beautify the surroundings.

Any number of other equally effective ways of utilizing the various kinds of nasturtiums are possible. The dwarf varieties which grow in a low brush-like form are effective as border plants or for bedding purposes. They are especially useful where space is too limited to allow for planting of the spreading sort. Even a small bed will furnish an abundance of fine foliage and gay flowers for indoor decoration. The comparatively new variegated kinds known as the silver and mosaic-leaved nasturtiums with their strikingly marked foliage are ornamental even when not in bloom. The dwarf kinds that form bushy plants about a foot in height may be used as pot plants

as well as for outdoor bedding. The new ivy-leaved nasturtiums have thick, lobed, dark-green leaves somewhat similar to those of the English ivy and bear a profusion of medium sized star-like flowers during the season. The petals of these flowers which are narrow and peculiarly notched are quite separated from each other giving the flowers a wide open airy appearance which undoubtedly suggested the name "Butterfly Nasturtium" by which this variety is also known.

The nasturtium is not at all fastidious. Given well-drained, fairly good garden soil and a sunny situation, a few weeks after sowing, the plants will begin flowering and will continue to bloom until heavy frost puts an end to the brilliant spectacle. Even in hot, dry weather, the nasturtium will thrive and bloom luxuriantly unless soil that is too rich encourages a rank growth of leaves at the expense of flowers.

For brilliant and varied display of color, wonderful shading and markings, duration of blooming season and ease of culture, the nasturtiums are unsurpassed. Few if any other garden flowers can be successfully raised with so little expenditure of time and money, for after the seeds are once planted little attention is required, though the plants respond promptly to cultivation and repay a thousand-fold by a profusion of attractive, spicy flowers from June until frosty weather, and if desired, sturdy plants lifted in the fall, or cuttings rooted in water or in sand, may be potted and taken indoors—a bit of Summer bloom to brighten wintry hours.

SCENTED MUSK

IN the vernacular, "Wot are yer bloomingwell giving us." *Florum Amator*?

To use an old saw, "All is not gold that glitters" and as far as offered seed of *M. moschatos* is concerned, all listed as such, is not necessarily scented.

Time was when I, as a kid, used to buy a fine pot of scented musk for "tuppence," but unless a new source has been discovered, I do not think it is possible in England now, not even at a "bob." *The Garden*, London, has discussed this subject more than once and only one person reported having a scented plant, a chance seedling in a bed outdoors.

If seed of the real thing were so easily obtainable, I guess *The Garden* would have run into W. & S. next door long years ago. But the trouble is that while true *M. moschatos* seed is easily obtained no seedsmen would back it to come scented. I used to grow the giant musk (Harrison's). This, too, seems to have lost its perfume, yet it was propagated from cuttings. It is years since I saw it.

It is just possible as *Florum Amator* suggests that there are two forms of *M. moschatos* but I have my doubts as to the scentless form being a run out British type; it is questionable whether seed as sold in England was ever grown in that country. Dare I hint that some wily "Yankee" put it over because it seeded more freely?

At all events, I'll just ascertain from my esteemed friend, J. M. Brideford of W. & S. where his true sweet scented musk seed comes from.

I might add that I have yet to see a plant of *M. moschatos* on this side of the water, either cultivated or wild.
—T. A. WESTON.

The Greenhouse, Month to Month

GEORGE F. STEWART

IN late August and early September, we are likely to have hot humid days and cool nights. The greenhouse man needs to be as wide-awake as ever, as at this season fungous diseases of all kinds are likely to get a foothold, and prevention is better than cure. Along the Atlantic seaboard heavy fogs are bothersome, making the atmosphere during the night quite damp. Every precaution should be taken to have all foliage in the greenhouse as dry as possible over night.

Chrysanthemums on single stems will have to be carefully looked after as regards feeding, and keeping insects in check. A careful study should be made of the proper dates to take the best bud. Chrysanthemum specialists, in their lists, generally give reliable information when they send out a new variety, and until one has his own experience with the variety, their advice should be followed. In the evening of the day after syringing, it is a good plan to take the powder duster and put some air-slacked lime in it to dust lightly under the foliage. In dull or wet days, give a light dusting of flowers of sulphur which will help to prevent mildew. Give the specimen plants plenty of room and disbud as soon as the bud can be handled. Stake or train them into position as soon after setting as possible. Feed carefully; we find the old standard fertilizer, "Clay's," as safe any any, with waterings of cow manure water.

Herbaceous calceolarias, as soon as the cool nights of September arrive, will begin to grow vigorously. Move them along into larger pots as they require them. A compost of fibrous loam, leaf mold rather flaky, osmunda fern root, well decayed barnyard manure and sand, in equal parts with a sprinkling of charcoal, we find agrees well with them. When potted, keep them close up to the glass and give all ventilation possible. Keep a light shade over them until the end of September. Stock plants of the *Stewartii* type of *Calceolaria* should be overhauled about the first of September. Remove all dead leaves and shoots, and pot them in a compost as advised for the herbaceous type. When a good soft growth is attained, cuttings may be removed and inserted in sand. Hard cuttings take a long time to root, while soft ones will root in three weeks. The old stools will make fine large specimens if potted along, and pinched several times during the Winter.

Never allow the cinerarias to become pot bound until the desired size of flowering pot is reached. Pot them in a fibrous loam, adding about a third of flaky leaves and rotted manure, and a sprinkling of bone meal. We have nice bushy plants by pinching out the heart when they are about six inches high.

Move along *Primula chinensis*, *obconica* and *stellata*, also *malacoides*. A late sowing of the last may be made around the last of August. Primulas do very well in loam similar to that applied for cinerarias.

Do not neglect the carnations which were planted early. See that they are wired, tied, and kept clean. A dusting of air-slacked lime over the surface of the bench will be beneficial. Do not think, however, of applying any plant food to them until the days are cooler. Stop all pinching of the flower stems by the end of August.

Shake out and pot up Calla lily bulbs in a rich soil to

which bone meal has been added. Leave them outdoors until there is danger of frost. Three to four bulbs to an eight- or nine-inch pot is about the right number. Of course, if bench space is available, better flowers are obtained by bench culture. The finest flowers I have ever seen were grown by a friend of mine on a solid bed.

Bouvardias that have been planted out should be lifted the last of August, or early in September. Place them in the shade until they have become established. Spray overhead lightly two or three times a day. They should be placed under cover by September 10. A fairly rich loam in which plenty of flaky leaves have been incorporated, adding sand enough to keep porous, is excellent.

A few of the late flowering cosmos may be lifted and potted for flowering indoors. They make handsome plants if they have been pinched one or twice. Choose a day for lifting them when they are quite dry at the roots so that they will transplant readily.

Early in September pot up whatever Canterbury Bells, *Campanula medium*, are required for early Spring flowering. Give them a slight freezing before housing them.

Buddleia asiatica may be potted into eight-inch pots and will make useful decorative plants during the Winter months. If one has a cold pit, batches of this useful plant may be had as late as the end of March.

Continue to plant batches of freesias for succession. The beautifully colored ones are best for late use. By keeping them just above freezing point all Winter, we can cut them as late as June.

Tritonia are very useful also for Winter flowering. About ten bulbs to a five-inch pot make nice plants. A good sandy loam is what they enjoy. The variety *crocata* is the most common one to be had.

Cut back show pelargoniums and when they begin to break, shake part of the old soil off and pot in a good rich loam in smaller pots, giving them a shift later on.

Sow seeds of a good strain of mignonette for Winter flowering; also *Calendula*, Lupin *Hartwegii* varieties, *alba*, *Celestinus*, *nigrescens*, which make handsome spikes for cutting in Winter. *Dimorphothecca aurantiaca* and the new hybrids are also attractive annuals for Winter flowering and may be sown now.

A sowing of stocks for Winter flowering should also be made at this time; also Winter flowering sweet peas in small pots. A place may be found for them after the chrysanthemums are gone.

All tender plants that are outdoors should be in a position to be housed hurriedly if a frost threatens about September 10 to 15, which is very likely to occur, about that time of the month.

Geranium cuttings, also coleus and other bedding plants should be secured by the last of August or early in September. Get as firm a cutting as possible. Give them a good watering when they are set in the sand, but do not water again until the sand gets quite dry. More geranium cuttings are lost by over-watering than by any other means.

Acacias and azaleas will be setting their flower buds, also camellias. It is better to stop feeding them with anything other than a watering of soft coal soot water occasionally to keep a healthy color on the foliage. Stimulating hardwood plants after they have set their flower

buds often causes them to drop the buds and start another growth.

Look over the begonias and where large specimens are wanted, give the larger and more vigorous looking ones another shift. Allow them plenty of room and keep well up to the light.

Continue to put in poinsettia cuttings, as late struck ones make beautiful low pans. A little heat at night in the tropical house will not be amiss by the end of August. If it grows too cool and damp at nights, fungous spots quite often appear on the foliage. It is also safer to have a little heat in the rose house at night with plenty of top air. Dust air-slacked lime under the foliage at night after syringing. Light dusting of flowers of sulphur over the bench occasionally acts not only as a preventative for mildew and other fungous diseases, but we have now found that there are fertilizing qualities in sulphur if not over done. A little scattering of bone meal on the benches will be beneficial and a little later on, a mulching of cow manure, providing that the plants are growing vigorously. Give plenty of air and water well when the manure is applied, which prevents the foliage from burning.

Plants in flower just now are allamandas, *Adamia versicolor*, anthuriums, dipladenias, *Medinilla Curtissii*, *Stephanotis floribunda*, *hamanthus*. They will finish their flowers within a short time and require drying off gradually.

Miltonia vexillaria will now need looking over and if any require potting, it should be attended to at this time. Fill the pots at least a third with drainage, as they are

shallow rooters. An intermediate temperature is what they should be given. Keep them at the closest end of the house after potting. Have them raised close to the glass and a moist atmosphere maintained. Fern root and sphangum moss make an excellent potting compost. Some people have great success by adding a little partly decayed oak leaves. Take care not to over water after potting.

Some of the odontoglossums and odontodas also need looking over for repotting, but as they flower over a long period, they cannot all be potted at once. Get them just as they are starting into growth. Use a compost as for vexilariums and treat similarly regarding watering and moisture. The temperature, of course, needs to be lower.

Some of the early flowering cattleyas are finishing up their growth. Give all the light possible without scorching the leaves. Keep *C. gigas* up close to the glass and near the ventilators, as they ripen their bulbs better in that way.

Pot vines that will be forced early will now be ripening their wood and need to be gradually dried off, but do not overdo it. Keep the wood firm.

The grapes are well advanced towards ripening and should have plenty of air. In the earlier stages of coloring a good idea is, about the hottest part of the day, to close the house down for about half an hour and lightly moisten the floor, and sweat the house slightly. This helps to bring on that rich bloom which all cultivators of the grape love so well to see. Great care must be exercised not to overdo by leaving the house shut too long, as it will do damage very quickly. These little tricks are all right if done by a careful man.

Cerastium and Sempervivum

RICHARD ROTHE

BELONGING to the order *Caryophyllea*, cerastiums are low growing, creeping Alpine plants, distinguished by silvery or grayish white foliage of small ovate lanceolate form. The handsomest of the gar-

flowers of cerastiums for near and distant effect are unexcelled.

Thriving best in rather light sandy soil and being very resistible as to prolonged droughts and mid-Summer heat, cerastiums are useful as ground cover on arid, sunny slopes. Collectors may be interested in the following species: *Cerastium alpinum*, identical with *Cerastium villosum*; *Cerastium Boissieri* and *C. grandiflorum*, the latter a silvery white, large flowering type of strong growth and about six inches in height.

(Continued on page 237)

Cerastium tomentosum

den species are *Cerastium tomentosum*, a native of the mountainous districts of Southern Europe, and *Cerastium Biebersteinii*, hailing from Caucasia. In gardens abroad both have been freely used for edging and for carpet bedding. We class both among the indispensables when planting open sunny rockgardens and dry walls. In vivid color arrays, vernal, pure white is a strong note. The blossoms of rockcress, hardy candytuft and *Phlox subulata alba*, vanishing away by the middle of May, those of the Cerastiums take their place. Light, fluffy, playfully moving in a gentle breeze, the glistening white masses of

Sempervivum arachnoides

EARLY-SPRING PANSIES

When pansies are mentioned we think of the familiar *Viola tricolor* sorts, which have long belonged among the most treasured of vernal plants in the garden. These, in the course of many centuries, have, through breeding of conscious aim, been perfected in extraordinary ways in form and in color and will perhaps always maintain their place in the garden.

Since a few years before the war, however, the pansy has met with a very noteworthy rival in the new forms of the horned violet, or tufted or bedding pansy, *Viola cornuta*, which not only strives, in form and in color, deceptively to imitate it, but in profusion and lasting qualities of bloom and in vigor also is superior to it. Up to the present we have for the most part learned to value the horned violet, only in its small-flowered forms, as a flowering plant of long continuance. Kinds like G. Wermig, in their deep violet-blue coloring and in their fullness of blossoming, which lasts from spring until into the autumn are quite unsurpassable. But the Wermig viola and similar sorts like *Papilio* still completely deserve the name violet, while the newer productions take on all the time more and more the character of pansies. The horned violet is a genuine shrub, and in these new forms are inherited all the good qualities of their ancestry. Even in an early spring as cool as that of this year the flowering of the early kinds began even in March, so that in more favorable years they right well deserve the name of "winter-blooming."

To these early sorts we should like for the present to direct attention. They are happy in any fresh garden soil, most so in porous loam and in a sunny site; only in places too dry and where the sun becomes hot is their culture not to be recommended. If it is desired to have them flower quite early in the spring they must be planted in good time in the early autumn in order that they may enter the winter as well rooted and vigorous plants. They may be left possibly three or even four years in the same place, if they are given annually, before their blooming, good liquid manure and in the fall a little mulching of well rotted manure. The growing of them from seed is just as easy and just as satisfactory as in the case of the *Viola tricolor* forms. Although the *cornuta* sorts are not yet so noble in structure of flower and in the gradations of coloring they are nevertheless being improved year by year. Had not the endeavors at breeding been disturbed by the war these new horned violets too would have been so perfected in every way that they would supplant the best pansies. But even as they are today they surpass true pansies not inconsiderably in their beginning to bloom earlier and in the longer continuance of their period of blooming. Their play of colors is not yet quite so rich, but at the same time the following list of sorts contains a rich selection of colors, to whose charming design and appealing form of flowers the pictures give testimony:

Cyclops, a quite new sort of dark and brilliant violet color, with white eye marked with black; Ice King, white with dark eye; Half-Mourning, a peculiar novelty, whose upper petals show a deep pansy-blue, while the lower ones are white; with a cream-yellow gleam and light blue lines; Jupiter, purple-violet, upper half of the flower whitish; March Wizard, soft velvety dark blue; Mars, ultra-marine blue; North Pole, snow-white; Winter Sun, golden yellow, with dark eye; Wodan, almost black. The growth of most sorts is compact as with the Horned Violet, whose characteristics especially come to the fore in kinds like Cyclops. In part the influence of *Viola tricolor* is more strongly expressed; in the rise of these new sorts it has had a part to such an extent that they may

rightly be called the pansies of the spring. They ought to be adopted everywhere into our gardens.—Tr. from *Gartenschoenheit* by F. B. M.

GARDENING IN SOUTH CAROLINA

(Continued from page 233)

progress, and this can be said of *Nordmanniana* and *concolor* fir, *sciadopitys* white and Austrian pines and certain varieties of *Retinisporas*, *squarrosa Veitchii* in particular.

The perennial border gives a lot of worry—a good many choice varieties such as delphiniums, Canterbury Bells, aquilegias and anemones do not feel at home. The hollyhock is the grandest of them all and perfectly free from disease. Fairly good success can be had though with the greatest care, if you see to it that the flowering period comes in as early as possible, April and May, which are the best months for perennials and the time to enjoy them.

Now for the lawn. An absolutely perfect lawn is next to impossible, but with a large percentage of white clover and a mixture of Kentucky blue grass, red top, fescue and bent, I manage to have a fair all year round evergreen lawn, sprinklers running all of the time.

Let me say finally that one of the main secrets in this section for success is to take advantage of a good season for planting and with great care your work will be successful—if I have been partly so it is because I have followed these rules, but after all the real pleasures of gardening are to be looked for in the more moderate climates.

SEMPERVIVUM

(Continued from page 236)

Cerastium, frequently called "Snow in Summer," may be raised from seed or propagated by cuttings or divisions during Spring or Fall.

Light covering throughout northern States.

SEMPERVIVUM—HOUSE LEEK

Sempervivum, a genus of the order Crassulaceæ, with numerous greenhouse and hardy species, mostly of low growing rosette shape is a special favorite of collectors. Of the hardy kinds quite a portion endures our most frigid Winters without any protection. Nestling between the stone work of old walls or in the crevices of rocks on sunny mountain slopes and ledgy plateaus we wonder how they can exist and grow with hardly any soil.

Sempervivums today represent a strikingly interesting material of odd character for both the rockery and the dry wall. For a minimum of care we may sometime enjoy the quaint picture of a plantation in full bloom, such as depicted by our illustration.

The number of species listed in trade catalogs of course is limited. Of those I have seen, I mention: *Sempervivum arachnoideum*, *calcareum*, *globiferum*, *Wulfeni*, *Funkii*, *tectorum*, *pittoni* and *robustum*. Of the very attractive red-leaved species *Sempervivum rubens*, or *rubicundum*, *triste* and *violaceum* seem to be obtainable.

The nomenclature of the Sempervivums is in a chaotic state.

Father had been cleaning the bedroom windows outside, when little Muriel came in from the garden, and said: "Mother, did you hear the ladder fall down just now?"

"No," replied the mother.

"Well," said the child, "it fell down and broke three flower-pots. I told daddy you'd be cross."

"Oh, dear," said mother; "I hope your daddy hasn't hurt himself!"

"I don't think he has yet," said little Muriel; "he's still hanging on to the window-sill."—Exchange.

Work for the Month in the Garden

SAMUEL GOLDING

THE work in the garden after this date, that is, during August and September, is of a routine nature, consisting of harvesting the ripened crops and encouraging in every way the growth of the plants which are for late Fall and Winter use. Plans should be made, and seeds sown for next Spring's flower garden. Early potatoes should be lifted as soon as they are ripe, and if there are signs of decay among the tubers, they should be placed thinly in a dry place with a little air-slaked lime scattered over them.

Harvest the onions as soon as the tops die off and the bulbs are thoroughly ripened. After they are pulled, spread out to dry, turning them over with a wooden rake, being careful not to bruise the bulbs, as this will impair their keeping quality. When dry, place in a dry airy shed until they can be stored away for Winter.

Celery will be growing apace and will need constant attention from now on. Keep it free from weeds; pull off the suckers or basal growths, and see that it does not suffer from drought. An occasional dusting of Scotch Soot is beneficial, and a dressing of some approved fertilizer will help to maintain a rapid growth. Watch carefully for the appearance of rust and spray immediately with Bordeaux Mixture if signs of it are found. Earth up some of the earliest at intervals, the amount of which should be determined by the expected demands.

Transplant lettuce and endive, and sow more string beans, for although it is late, should we have a warm Fall, they may mature. Also sow French forcing carrots, beets and turnips. In September prepare and sow in cold frames for successional batches those vegetables above mentioned, so that when frost threatens the sash can be placed on for protection. As soon as the onion and the early potato crops have been removed, this space makes a good place for late spinach. The prickly seeded variety is very good for this work as it is very hardy.

Sow cauliflower and cabbage in September for next Spring's use, wintering it in the cold frame.

Thin out seedlings from last month's sowing when they can be conveniently handled. At this time of the year things grow rapidly and soon suffer if allowed to become crowded.

Tie up enough endive to blanch at intervals of about ten days, to meet the demands for that time. If more than can be used is tied, it may decay, especially so if the climatic conditions are humid.

Transplant parsley into cold frames for Winter use. Give the green crops a dressing of nitrate of soda. This is an excellent stimulant but should be used with caution.

In many localities good farm yard manure is becoming more and more difficult to obtain and each succeeding year finds it less plentiful, with a corresponding increase in price. Consequently the value of a cover crop is being more appreciated and is proving a good substitute. When the land is cleared of crops sow a mixture of rye and "Hairy Vetch." This will soon make good growth and if dug or ploughed in next Spring, will ensure a good supply of organic matter and nitrogen to the soil.

Cut out all old wood from raspberry plantations. From now on and throughout the Fall until the first killing frost, the flower garden will be ablaze with a galaxy of color. The dahlia will be at home now and

should have every encouragement if we would have the best. Dahlias should have an abundance of moisture with some liquid manural waterings at intervals; if the weather is dry, disbud early, tie and stake securely. See that gladioli are properly staked, otherwise the spikes are easily ruined. Late asters, scabiosas and other annuals, will repay attention of good staking where it may be needed. This may be done early so that by the date of blooming the stakes are quite hidden by the growths. See that the beds and borders do not suffer from drought during August so they will be carried on in good condition throughout September.

Prepare the propagating bench to receive cuttings of stock for next year's bedding, including coleus, fuchsias, heliotrope, lantanas, alternantheras, and other soft stock. Sow pansies, English daisies for Spring bedding, and also a full line of perennials in the cold frames for use in the borders next Summer.

Keep the rose beds free from weeds and spray with Fungine if mildew is prevalent. Tie the ramblers in position so they can have the full benefit of sun and air, and that the wood may be thoroughly ripened as it will then be in a better condition to withstand the rigors of a severe Winter.

Any alteration in the peony garden should be done early in September in order that the places can be prepared now for the reception of the new varieties, which were probably ordered during peony time last May.

The chaste Madonna Lily should be planted as soon as possible for the best results. Many other varieties of lilies are incomparable for garden decoration at this time. They compel attention in almost any situation and are easy to grow if the land is fairly well drained. They are partial to leaf soil but impatient of strong manures.

The bulbs also should be planted as soon as they are received from the dealers, as they shrivel if exposed to the air and their vitality becomes impaired. Order now the bulbs from your dealer for next Spring's display. If notes were taken during the flowering time they will be found of much value when going over the lists, as mistakes of the past can be avoided if varieties and quantities were noted.

Early in September is a good time to move and replant evergreens. The climatic conditions will necessarily have some influence when this should be done, as it is a great advantage if transplanting can be accomplished during showery or dull weather. They should not be allowed to suffer from drought. Root action will soon commence after careful planting at this date.

This is a good time to carry out any renovating and reseeding of lawns or making new lawns, as generally there is more time to carry out the detail work than prevails during the Spring rush. The ground should be ploughed or dug over as early as possible. This will give the weed seeds an ample opportunity to germinate and are then easily killed by going over with the cultivator. Grade and level the surface, raking it over to make it friable for the reception of the seeds. Choose a calm day for sowing as it is then easier to get an even stand. If we have showery weather germination is very rapid, but if the weather is dry, artificial watering should be resorted to so that the lawn will be established before Winter comes.

WISTARIAS

AMONGST vigorous climbing plants there is nothing more beautiful than a well developed Wistaria in full blossom, particularly when it has been allowed a good deal of freedom, and has rambled over a tree or large building practically unchecked. Wistarias are easily grown and hardy enough for wall cultivation throughout the greater part of the British Isles, while in the warmer parts they succeed admirably in the open, given a large bush or tree over which they may ramble. The genus contains but a few species, and of these two are so superior to the others in general worth that they are almost exclusively chosen. They are amongst the most popular of all climbers for planting on verandas and pergolas, for in these positions the long, drooping racemes of fragrant flowers are seen to the best advantage, whilst they are also suitable for many other positions. Given moderately good and well-drained, loamy soil, their cultivation offers no serious problems, for they grow well from the time they are planted. Soil of a very rich nature may result in too luxuriant growth and moderate flower production; therefore, it is unwise to manure the ground heavily in which Wistarias are to be planted. Moreover, in places where the root-run is restricted flowers are usually produced more freely than where there is an unlimited area of good soil. Free-growing plants against walls have to be pruned to keep them within bounds, and in such cases it is wise to encourage a system of short, sturdy, spur-like growth, such as may be seen on stunted plants grown in pots for greenhouse decoration in Spring. Constant cutting back of secondary branches may be expected to result in growth of this description. The same remarks apply to plants grown on pergolas, but when growing freely over trees or large bushes pruning may be left entirely alone. There are several means of propagation. Branches may be layered into sandy soil. Cuttings of ripe shoots a foot long may be inserted out of doors in Autumn, or shoots may be grafted indoors in Spring upon sections of root.

W. chinensis is the most familiar plant. It is a native of Northern China, and was originally grown in this country about a century ago. It is capable of reaching the top of very high buildings or covering large trees, but by a system of root restriction it can be grown for many years as a bush a few feet high, and be expected to flower freely each Spring. The flowers are mauve in color, very fragrant, and borne in racemes each 8 inches to 12 inches long.

W. multijuga.—Although not so well known as *W. chinensis*, this is an equally desirable plant, and is particularly well adapted for planting on pergolas and other supports, where its racemes can be displayed to the greatest advantage. It is very popular in Japanese gardens, and is introduced in works of art by Japanese artists. It is said to have been introduced to European gardens by way of Belgium soon after the middle of last century, but it has only attained popularity in the British Isles within the last thirty years. It grows almost as large as *W. chinensis*, and is rather similar in leafage, but has much longer and less dense racemes of fragrant mauve flowers. The racemes are often between 3 feet and 4 feet in length, and are produced with the greatest freedom.

W. brachybotrys, *W. frutescens*, and *W. Japonica* are other species that have been described and are occasionally cultivated. They, however, are quite overshadowed by *W. chinensis* and *W. multijuga* for general purposes, and can only be recommended for gardens where a collection of species is desired.

Early in July the shoots produced by the main or leading stems should be pinched back to within a foot or little more of the main stem, in order to check the rampant growth. These shoots will again break into growth from the buds behind where the shoot was stopped, and after these shoots have grown a few inches they should also be stopped. The result of this will be the production of flower-buds at the formation of the shoots first stopped. Early in the following Spring these shoots should be cut back to within five or six eyes of the main stem, the young growths from these eyes to be treated as those of the previous year. By treating in this way long racemes of flower will be produced.—Gardening Illustrated.

COMMON-SENSE PRUNING

IT is decidedly encouraging to see signs appearing of more common-sense methods of pruning amongst our modern horticulturists. I have been pleading for more reasonable and more scientific methods for many years, and I was particularly pleased

to see that your correspondent, "A Scottish Gardener," describes the old methods as barbarous. He is quite right; and it is rather strange that many intelligent gardeners do not discover for themselves that the pruning of fruit trees on the same plan as the trimming of a garden hedge is not the way to produce abundant crops of good fruit. I am sorry, however, to see that "A Scottish Gardener" falls into the common error of stating that if a shoot is pinched back, "the sap would be diverted to other portions of the tree where it would be of more service." Such an idea is entirely erroneous, and until some of the old fashioned ideas about "sap" are got rid of progress with scientific pruning and treatment of fruit trees will be slow.

As a matter of fact, sap cannot be so diverted. It is quite true, of course, that if any of the branches of a tree are removed while the roots are untouched, the root system is then larger in proportion to the branches than it was before, and is therefore capable of supplying more water and dissolved soil food to the tree—if it requires it, or if it can use it. But this is the crux of the whole matter. A plant cannot make any use of the sap—that is, of the soil food—unless it has leaves in which to use it—and the very fact of removing the leaves by cutting off a shoot prevents the sap being utilized.

The sap taken up by the roots consists of a very watery solution of chemicals—that is, of various salts of phosphoric acid, potash, lime, magnesium, etc., some of which are in the form of nitrates, and these salts are dissolved in at least 1,000 times their weight of water. Before these salts can be of any use to the plant they must be carried up to the leaves or other green parts of the plant, where, first of all, the surplus water is got rid of by evaporation, and the salts are then built up by the living cells of the leaves into proteids and other materials used by the plant in its growth. At the same time the leaves and other green parts are manufacturing starch and sugar from the carbonic acid of the air, and some of the water; and this, along with the materials elaborated from the salts brought up from the roots, is then carried, mostly downwards in the bark, to where it is required for the formation of new shoots, leaves, buds, fruit, wood, and roots. If the plant is strong and vigorous, more of this elaborated material is made than is necessary for the daily requirements of the plant, and this surplus is stored up for future use in the bark and in the medullary rays of the wood.

It is from this stored-up material that the plant starts to swell its buds and produce new leaves and roots in the Spring, and not from any flowing of the root sap, as is commonly supposed. I was very pleased to see this fact recognized by one of our well-known horticultural writers the other day, who seemed to have been convinced of the truth of it by observing that a cut-off branch can produce new leaves, and even flowers, without any connection with the soil at all, and therefore without any flow of sap.

These things are worth thinking about, and any practical gardener who thinks them over must see how they bear upon pruning. If the leaf-bearing area of the plant is too much reduced, it stands to reason that the plant is unable to make enough starch and sugar, or to get rid of the surplus water in the sap, and to build up enough proteids and other materials that it requires. It therefore has none to spare for storing up, or even for making fruit buds, well-ripened shoots, new wood, and new roots. It may not have sugar and other materials to put into the fruit it happens to be bearing. It is true that a plant may be producing too much growth; but this is generally due to the soil containing too much nitrogenous plant food, and the plant, with that eye to the future which it always has strongly developed, is bent on making all the growth it can while the favorable conditions last. But the gardener is after fruit, not luxuriant growth, so he checks this by curtailing the supply of stimulating food by root pruning. He is working at the wrong end if he lets the tree take up all the soil food it can, and then attempts to check it by removing the foliage, so that it cannot manufacture the necessary starch, sugar, proteid, etc., that it needs for the production of healthy wood, new fruit buds, and ultimately fine fruits.—Gardening Illustrated.

LARGE-FLOWERING PANSIES

MUCH has been written concerning the culture of Pansies, but this has been mainly concerned with Spring sowing and Summer and Autumn flowering. A few observations should now

be pertinent upon Summer and Autumn sowing and early Spring flowering, which last desirable occurrence may readily be extended into Summer and Autumn if the plants are well grown and the flowers cut regularly and often.

There is greater merit in producing Pansy plants that flower in early Spring than those that bloom at any other time. The blossoms are always larger, for they obtain the benefit of the moist soil and moderate Spring sunshine, whereas the later blossoms may have to endure drought and scorching sunshine, neither of which suits the Pansy.

Let it be understood that *large* flowers are under consideration. Pansies will, of course, grow almost anywhere, but large blooms can only be produced with good culture, a suitable site, a rich soil and a sufficiency of moisture. Good Pansies will not tolerate extremes of either heat or moisture or the lack of them.

The first essential is a good seed-bed, and nothing would be better than the ground from which early Potatoes or Peas have been removed. This dug over, levelled and raked finely, forms an ideal place wherein to sow Pansy seed. The incorporation of leafy or fibrous substances with the surface soil is very desirable, as this keeps the soil porous while allowing it to be made quite firm, and it also affords a nutritious roothold of which Pansies are not slow to take advantage, for there are always some of these leaves attached to the roots when the plants are lifted for transplanting.

No particular time for sowing need be considered if it is done before August departs. Good seed is rather the next consideration. Well known strains should be used, especially those of English and French growers noted for their concentration upon the large flower. These seeds are usually of a mixed nature, for the Pansy produces such a variety of color shapes and markings, and each combination is so interesting that its absence represents a real loss. Of course, there are self colors—in white, yellow, blue, purple, red, black; and there are some strains that produce one prominent color in various shades. Such are the wine-stained, the blood-red Victoria, the terra-cotta Meteor, the silver and gold-margined and the bronze Pansies. These, with a mixture of blue shades, could be obtained and added to any other good mixture of blotched, veined or self-colored flowers, until one has *every* color among one's collection, with every conceivable color marking upon the flowers. I doubt whether any other flower could show such an extensive color gradation.

Early thinning must take place when the seedlings are large enough; delay will spoil all chances of good growth. Each plant should be given at least a square foot of soil to itself at the earliest moment, for Pansies make a very large ball of roots. The thinnings, of course, will be transplanted into rich, firm soil elsewhere. Throw nothing away, for may they not contain the very best types? Give *every* plant the opportunity to flower if room can be found for them. Many of them will flower in the seed-bed; indeed, in mild weather, if the plants have been encouraged to forge ahead, there will be flowers ready to cut at Christmas! If some of the seedlings are potted up, too, and taken into the greenhouse, they will flower earlier still, especially under the influence of a little warmth and a light position near the glass.

When planted in beds or borders in the early Spring, care should be taken to lift the plants with a good ball of earth, so that they receive no check. If planted well, flowers will soon make their appearance, for the plants will be full of buds.

A moist, retentive soil in an open position should be chosen. Pansies are sunshine lovers. Evidence of that will be found in the fact that the flowers will always be facing the quarter from which the sun shines most; therefore a sunny site is an advantage if adequate moisture can be guaranteed. But a sun-dried position is certainly detrimental, and a very wet soil will cause the plants to die away.

Cuttings may be taken from any particular color that may appeal to the grower as worth perpetuating, for seeds, of course, give no guarantee in this respect. Plants from seeds, however, undoubtedly yield the largest flowers.—H. A. DAY in *The Garden*.

HINTS ON FIG CULTURE

GIVEN good management, the fig, when grown under glass, yields a larger quantity of fruit than any other fruit-tree in cultivation. Though needing proper treatment, the fig does not require the same close care and attention in its culture as the vine does, for instance. Then, it is so constituted that two crops of fruit may easily be obtained from trees grown in a suitably heated structure. Artificial warmth need only be employed for the production of the first crop, as the husbanding of solar warmth in a normal season suffices to bring the second to maturity.

When the fruits are required in quantity, the best way to secure them is to set a house apart purposely for the cultivation of the trees. This proves a more satisfactory method than endeavoring to produce them under the dual system, as is often seen practiced

when the back walls of vineries and peach-houses are clothed with fig-trees. When so cultivated, the results are variable. The structure for this purpose may either be in the form of a lean-to or span-roofed, and, as regards the trees, they can be planted out and trained on a trellis under the roof-glass, or, if so desired, grown in pots or tubs, as bushes. By either method heavy crops of fruit can be grown, the balance being in favor of trained trees in regard to actual numbers. One thing in favor of the bush system is that, after the trees have ceased bearing for the season, they can be moved outdoors until they have shed their leaves, and then can be wintered in a cool, dry, close shed or stable, where, if well surrounded with dry litter or bracken, they will be secure from severe frost. This proceeding enables the house to be used for other purposes until it is necessary again to bring in the figs and start them into growth.

An excellent way of training the fig, when the trees are planted in a border, with their roots restricted to a certain area, is to reverse the usual order of things, and, instead of planting them at the front of the house, to do so at the back, and train them downward from the top of the trellis to the bottom. This leads not only to increased fruitfulness, but it always ensures a short-jointed growth. It should, perhaps, be mentioned that the first crop of fruit, though finer individually, is never so great in point of numbers as is the second. Trees trained for either purpose are to be had from any nursery where the growing of fruit-trees is made a specialty, or if cuttings can be had, a stock of trees can be worked up in a couple of seasons. They are easily propagated, and the early months of the year are the best time to effect this. A gentle bottom-heat, such as is afforded by the plunging-bed in a forcing-house, facilitates their rooting, after the base of the cutting has become callused. The advantage to be gained by early propagation is that good-sized trees can thus be secured the first season. The wood selected for cuttings should in all cases be thoroughly ripened. The trees intended for training under the roof may be planted after they have made about five good growths. This necessitates their being shifted from the pots in which they are struck into others 7 inches or 8 inches in diameter, before they are in fit condition, or have made the required amount of growth.

Bushes of good size will result the first season if due attention is paid to shifting the plants on from the cutting stage when rooted, first into 5-inch and finally into 7-inch and 8-inch pots; also in stopping and regulating growth, with the object of obtaining open, well-balanced heads.—*Gardening Illustrated*.

TREE-PÆONIES

THE Tree-Pæony may be regarded as the prince of deciduous flowering shrubs. What it may become in course of time may now and again be gathered by a fine bush of *Pæonia arborea*, some specimens having attained about 4 feet high and a similar diameter across, and providing their owners with a rich display of blossoms. How few of such examples really exist is not altogether due to the plants having been planted with a meagre hand; rather is their scarcity due to varying circumstances that have ensued from time to time. Nor must it be taken as a sign that these plants are not suited to our climate, for I believe there are many gardens that could grow them well, were a little more attention bestowed in selecting the site. Formerly the question of position was not sufficiently regarded by those to whom the planting was entrusted, and so it not infrequently occurred that the plants were not given the best position in the garden. The question of position is important, and this is enhanced when we remember how impatient these plants are of removal. Then, again, when attention was given to the position at all, it was usually a sunny one that was selected, and this is, I believe, far from being the best for this group. And how much or how little these plants are affected by position is due to the susceptibility of the plant to be cut back by the late Spring frosts. Though enduring all the frosts of Winter with impunity, which never in the least degree harm them, the fresh young shoots are among the first to feel the chilling effects of frosts in the Spring of the year. And not only leaf-points, but flower-buds, always so closely associated with the bursting leaves, are affected, and sometimes disastrously. It is always more disastrous in results when the plants occupy a south or south-easterly position, for the sun strikes the plants before the frost is gone, and the work of disaster is more quickly completed. Bad as all this appears at sight, it is rendered worse by wrapping the plants up in thick matting for the Winter, a proceeding that only makes the young growers even more tender and susceptible to cold, all of which may be avoided by planting these shrubs in a westerly position—either this or north-westerly. In either of these positions the plants remain quiet through the Winter, and, with the arrival of Spring and those damaging frosts that are of almost annual occurrence, these Pæonies, being more or less dormant, remain unaffected. If the Spring be very late, the plants almost invariably escape because of the protection the position affords, as before the sun reaches the plants all the frost is

dispelled, and it is not merely the disappointment at the failure and the loss of bloom when these plants are yearly cut down by frosts, but the loss of growth that is constantly occurring to the plants, thus preventing them making much headway. So wonderful a group of plants is worth every care to bring it into good condition. Above all, attention should be paid to the drainage, for, if the subsoil is continually wet, there is not much hope for long-continued success. In such instances it will be best for the bed or border containing the plants to be raised above the ordinary level, inserting as drainage, clinkers or like material below. A word as to

PLANTS AND PLANTING. If the original kind finds favor, the ground line for planting will be somewhat clearly defined; but if some of the modern named sorts are being taken in hand it will be seen these are either grafted or budded, the point of union being a rather delicate and frail one. In all cases where this is possible, however, the plant may be buried so as to cover the point of union, and if at the time the bark be nicked or cut with a knife 1 inch below the graft, fresh roots will be emitted sooner or later, and provide a greatly increased support to the plant. Those who are making a start with these lovely plants cannot do better than devote a small bed to them where their wants may receive attention. The blossoms are often each 10 inches across, and in double or semi-double kinds. As to colors, these embrace the purest of white, lovely and exquisite rose shades of glistening satin hues, beautiful shades of pink and cerise, lake and lilac, to say nothing of mixed colors in great variety.—*Gardening Illustrated.*

[In the United States Tree Pæonies do not do well north of the latitude of New York City, except in the Puget Sound region, nor in the central west, where the summers are hot and dry. They are best when grafted upon roots of the herbaceous,—not *officinalis*, however. For the first year or two the union must be near the surface of the ground. After that they may be planted deeper and then they will start to form roots of their own.—*Editor.*]

GARDEN REFUSE

I suppose one of the principal jobs in the kitchen garden is the process of clearing up. There is a lot of what is deemed rubbish or waste, and this has to be gotten out of sight somehow. A cardinal fact that you and I ought to remember is that there is no such thing as "waste" in Nature. It may not be a strictly accurate scientific fact—I do not know—but we might generally take it that anything which has possessed life possesses life-giving properties up to a certain point, and we are on absolutely sure ground when we say that vegetable refuse certainly does possess those properties. It may be thrown in a heap to decay, it may be burnt, it may be buried—those properties are still there, and in some way or other they will act. We want, then, to make sure we do not lose them, but conserve them for our use.

Perhaps the best and cleanest way of dealing with garden refuse is to burn it, and many gardeners avail themselves of this method. There are hundreds of fires on allotment gardens within the radius of two miles from where I write, and their flames at times illuminate the hours of dusk. But there are right and wrong ways of burning rubbish, useful ways and wasteful ways, and the wasteful way is to let it go up in flames and lose much of its value in the atmosphere. To reduce rubbish to ashes as quickly as possible is a wasteful method. It should be induced to *smoulder* to ashes rather than to burn, and this can be done by getting a fairly strong body of fire from the more easily inflammable portion of the refuse, sticks, etc., then piling on the bulk and banking it down with the heavier material, or even with earth. The more valuable elements are not then destroyed, but are conserved, and the ashes are left rich in mineral matter—real plant food. The gardener who thus disposes of his refuse and judiciously uses the ashes on his soil very seldom has to purchase that essential but expensive chemical known as potash. It was this very chemical which made the land in portions of North America so exceedingly fertile after the forests has been uprooted and so much of the "trimmings" and unprofitable lumber had been burnt and incorporated with the earth. I want you all to know the value of such ashes, and when you do you will not waste them, but rather gather them together and take care of them until you are ready to enrich your soil with them.—*Gardening Illustrated.*

TEXTBOOK OF LANDSCAPE GARDENING. by Frank A. Waugh. John Wiley and Sons, Inc., New York.

The publication of this work is a big stride toward the goal the attainment of which must seem desirable to readers of magazines like this, probably without exception. That is the putting into the curriculum of all schools of the liberal arts at least an elementary course in appreciation of landscape. In this way would be realized the profound conviction of the poet Wordsworth expressed in the words: "Laying out grounds, as it is

called, may be considered as a liberal art, in some sort like poetry and painting; and its object, like that of the liberal arts, is, or ought to be, to move the affections under the control of good sense." This quotation was used by Professor N. S. Shaylor in the *Atlantic Monthly* of the year 1898, in an article worth reading again and again, "The Landscape as a Means of Culture." The dicta of that essay, consciously or unconsciously, seems to have been in the mind of Mr. Waugh in writing the book now before us. He states that it is "designed for the instruction of non-professional students in landscape gardening, that is for those who do not intend to become professional landscape gardeners," and modestly adds that at the same time he "hopes that the book will not turn any good men away from the profession." It certainly will turn some into that one of the finest of all professions.

Its definite objects are: To teach the principles of universal art, *viz.*, the principles of order and design; to give a working understanding of these principles as applied to the art of landscape gardening; to apply the principles of landscape gardening to the domestic problems of the average citizen; to arouse an intelligent and constructive interest in civic problems; to bring the student into intelligent contact with the natural landscape; to indicate the great personal and social value of the landscape and to suggest what should be done by nations, states and communities for the preservation and use of the natural landscape. For accomplishing these objects the book is divided into lessons each of clear-cut topic, definitely and systematically outlined, illustrated by one-hundred and sixty-eight appropriate pictures or other figures, with problems to be solved and questions to be answered by the student. These lessons begin, as Professor Shaylor advises that studies in landscape should begin, with the "more domesticated parts" and thus prepare the student to understand, with Plato, that "the greatest and fairest things are done by Nature and the lesser by Art."

So concrete and "practical" are most of the lessons, all except the last few, that a more appropriate name for the book would probably be a "Textbook of Landscape Architecture." The text ends with three chapters that are very instructive and give grounds for the belief that the American people are actually upon the way toward using the "Landscape as a Means of Culture," and of the purifying and ennobling of life. These chapters are entitled National Parks and Forests, State Parks and Neighborhood Parks. In the first two are made accessible lists of the great public parks the mere names of which, to say nothing of their immense areas and wonderful natural treasures, are known to only a comparatively few citizens of the country.

The book is handsomely made, with type large and clear. Of the misprints, most of which are unimportant errors in the spelling of names, the only serious one is the interchange of the text of pages 149 and 150. What is printed as page 149 should be read after page 150.—F. B. M.

INSECT PESTS AND FUNGUS DISEASES, by Percival J. Fryer, F. I. C., F. C. S., Cambridge University Press, London.

It is probably safe to hazard the statement that for many years there has appeared no European book of more practical and economic value to American horticulture than this work of a man who occupies a very responsible position with a large English firm of manufacturing chemists. For sixteen years he has given particular study to the subject of fruit pests and diseases. Although in this his interest has been primarily that of the chemist he has familiarized himself with the entomological and the mycological aspects also. Every one of the 728 pages seems to have been done with the utmost care and confidence is inspired by the make-up in general. It is logical and concise. It begins with a review of plants' structure and habits and with a section devoted to the chief characteristics of insect pests. Then the heart of the work consists of a detailed description and treatment of each insect, some of which infest more than one kind of fruit. But any inquirer wishing to learn about an insect that may infest any particular fruit will have no difficulty in determining what insect it is by means of the drawings and colored plates. Of the 305 figures in black and white each one appears to be clear and adequate. The twenty-four full-page colored plates, each picturing from three to thirteen caterpillars, moths, insects or fungi, are eminently successful works of art. For more complete instruction there is an account of insects friendly to fruit growers. Fungus diseases are handled with the same precision and exhaustiveness as are insects. Though for each pest are assigned methods of prevention or extermination in the section devoted to it there is a complete section devoted to an orderly treatment of spraying and all its sub-topics. The index, listing both the fruits and the pests, is apparently perfect. All in all it is a work that though written for England should be accessible to every commercial grower of fruit in America, if not to every grower of fruit anywhere.—F. B. M.

Tell success stories, not incidents of failure and hard luck. Radiate prosperity, feel prosperous, it's catching. Keep your chin up.—Dr. Frank Crane.

LOCAL BRANCHES

Newport, R. I.: Andrew L. Dorward, chairman; Frederic Carter, secretary.

St. Louis, Mo.: George H. Pring, chairman; Hugo M. Schaff, secretary.

Nassau County, L. I.: John T. Everett, Glen Cove, chairman; John McCulloch, Oyster Bay, L. I., secretary.

Boston, Mass.: Robert Cameron, chairman.

THE COMING BOSTON CONVENTION

September 12, 13, 14, 15

A WELL attended meeting of the local branch of the national association was held at Horticultural Hall, Boston, on July 28. Members were present from Hingham, Wellesley, Natick, Manchester, Prides Crossing, Ipswich, Waltham, Beverly Farms and various points in greater Boston. Robert Cameron, president of the national association, opened the meeting and called on W. N. Craig, general chairman of the convention committee, to take charge of the meeting. Reports from the finance, transportation, and other committees were all very promising.

It was voted to select the Brunswick Hotel, Boylston Street, for convention headquarters. Rates at this hotel are as follows:

Double rooms accommodating two persons with private bath, \$6 and \$7 a day; without bath but with running hot and cold water in the room \$4.50 to \$5 a day.

Single rooms, accommodating one person, \$3.50 to \$5 a day with private bath; \$2.50 and \$3 a day for a court room with running hot and cold water, but no bath; \$3 and \$3.50 a day for an outside room without bath but with running hot and cold water.

Street cars pass the hotel from all parts of Boston and surroundings. The hotel is but a couple of blocks distant from the Back Bay Station of the N. Y., N. H. and H. R. R., and the Trinity Place station of the B. and R. R. R.; is within a stone's throw of Copley Square and the Boston Public Library and very conveniently situated for the meeting place in Horticultural Hall and the heart of Boston. There are a number of other splendid hotels very close to the Brunswick including the palatial Copley Plaza, the Lenox, Westminster, and Copley Square.

Dining room facilities at the Brunswick are unequalled in Boston; at the beautiful Flemish Cafe club breakfasts are served from \$50c to \$1.00; special luncheons at \$55c and 85c; and special dinners at \$1.25 and \$2. Unequaled in Boston also is the extensive a la carte bill of fare. There is a splendid cafeteria, old Dutch in style, where the best of food is served, well cooked, at popular prices.

The Boston Public Gardens, Boston Common and palatial Commonwealth Avenue are all within a stone's throw of the Hotel Brunswick. Those planning to attend the convention should bespeak room well in advance, or ask W. N. Craig, chairman of the local convention committees, to do so. All conventionists should report that they are members of the National Association of Gardeners and they will be extended every courtesy.

Some changes and additions were made on the program for the outing on September 14: automobiles will leave not later than 9:30 for the North Shore trip. Amongst other stopping places will be Orchidvale, Beverly Farms, which Albert C. Burrage cordially invited members to visit and inspect the greatest amateur orchid collection in America; the residences of Mrs. Gardner M. Lane at Manchester, Judge William H. Moore and Mrs. Henry C. Frick, Prides Crossing, will also be visited. Leaving there the ocean route via Magnolia, Marblehead, and Gloucester will be followed to Castle Hill Farm, Ipswich, the residence of Mr. and Mrs. R. T. Crane, where a real New England clambake will be served with all the fixin's. On the return journey, Cedar Acres, Wenham, Mass., the noted gladioli and dahlia farm of B. Hammond Tracy will be visited and various spots of historic interest will be passed en route to Boston.

A very full day is planned for the concluding day of the convention which will include part of the Boston Park System, the Arnold Arboretum, Agassiz Museum, and the world famed glass flowers at Harvard, historic Concord and Lexington; the Walter Hunnewell estate, Wellesley, with its matchless collection of rare and unique trees, shrubs and rhododendrons; and the extensive and beautiful H. H. Hunnewell estate where luncheon will be served.

The local committee would suggest to all planning to come from New York, Philadelphia, Pittsburgh and the West to take the outside S. S. line of the Eastern Steamship Corporation from New York for Boston, going by way of the Cape Cod Canal as a cool, comfortable and most delightful route. All railroad travel is avoided here, street cars may be had at the wharf which will take conventionists to the Brunswick or any other hotel preferred.

Mayor James M. Curley will speak to the convention and welcome members on behalf of the city of Boston. Albert C. Burrage will extend the greetings of the Massachusetts Horticultural Society and there will be other prominent speakers.

Various unique features are being planned by the entertainment committee and the ladies will all be well cared for. Boston hopes the 1922 convention will be a record breaker in points of attendance, general enthusiasm, and deeds accomplished. The old Hub of the Universe will warmly welcome everyone and endeavor to make their visit pleasant and profitable. Come therefore to New England's capital and see some of the glorious sights of America's greatest vacation land.

The next meeting of the local branch and committees will be held August 18.—W. N. Craig, Chairman, Convention Committees.

Members intending to attend the convention in Boston should communicate with W. N. Craig, Faulkner Farm, Brookline, Mass., to have him reserve the hotel accommodations for them. Mr. Craig in the foregoing article names the rates of the rooms, and in writing Mr. Craig, particulars should be given as to the kind of room that is desired. It is necessary to make reservations well ahead of time as several other conventions are being held in Boston at the same time as the gardeners' convention, which, of course, will make a demand for hotel accommodations.

Members desiring to go by the outside route of steamers to Boston, on Monday, September 11, can obtain full particulars by addressing the secretary, M. C. Ebel, 286 Fifth avenue, New York.

In order to register at the convention to secure proper credentials to attend the outings, members must show their 1922 membership cards, so please bring them with you.

AMENDMENTS TO THE BY-LAWS

THE following amendments to the By-Laws are to be submitted for action at the Boston convention:

We, the undersigned Branches of the National Association of Gardeners, being of the opinion that the increase in the life membership dues will act as a deterrent to the increase of the Reserve Fund and also being of the opinion that this Fund should be materially increased each year, do respectfully petition that the following amendments be made to Article VII of our By-Laws.

ARTICLE VII

Change Section I to read:

Section I. All moneys collected from life-membership dues shall be placed in the *Reserve Fund*.

Add Sections II, III, IV and V to read:

Section II. Ten per cent of all moneys collected from active, associate, and sustaining membership dues shall be placed in the *Reserve Fund*.

Section III. All investments of the Association shall be considered a part of the *Reserve Fund*.

Section IV. Yearly interest accruing on the *Reserve Fund* shall be applicable to the fund, or the whole or any part of said yearly interest may be extended for specified purposes on the advice of the Trustees subject to the approval of the Association at its Annual Convention.

Section V. The principal of the *Reserve Fund* shall be held intact.

Approved by the Newport Branch, March 22, 1922.

Approved by the Boston Branch, June 30, 1922.

ARTICLE VIII

LOCAL BRANCHES

RULES AND REGULATIONS

Section 1. The object of the local branch is to establish a closer contact between the individual member and the main organization, and to spread a better knowledge of the aims and objects of the National Association of Gardeners amongst non-member gardeners and others interested in Horticulture.

Section 2. Six or more members of the National Association of Gardeners may organize and form a local branch designating the branch after the district in which they are located.

Section 3. On organization each branch shall appoint a chairman and a secretary, and notify the secretary of the National Association of Gardeners of their action giving the names of the officers and the number of members composing the branch.

Section 4. Meetings shall be held as the members may determine and may be of an informal character. Non-members present may enter into discussions but cannot vote on any question.

Section 5. Each branch shall be entitled to send a delegate to the Annual Conventions of the Association. Any branch unable to send a delegate owing to distance or other causes may be represented by a member of another branch.

Section 6. A delegate on arising to address the Convention shall preface his remarks by stating the name of, and the number of members in the branch he represents.

Section 7. Applications for membership in the National Association of Gardeners coming from a district in which a local branch is organized must have the endorsement of that branch.

Section 8. It shall be the duty of committees appointed on important matters at the convention to ascertain, through correspondence with the secretaries of the local branches, the sentiment of the members on the matter in question and base their reports on the consensus of opinion so obtained.

Approved by the Newport Branch, March 22, 1922.

Approved by the Boston Branch, June 30, 1922.

COLLEGE COURSE FOR GARDENERS

Members expecting to take the college course on gardening this fall, as outlined in the July issue of the *CHRONICLE*, which is to be conducted by the Massachusetts Agricultural College in co-operation with the National Association of Gardeners, should communicate with Prof. Frank A. Waugh, Amherst, Mass., who will supply all the necessary information.

MELROSE HIGHLANDS, MASS.
August 1, 1922

Dear Mr. Ebel:—

I have been reading with a great deal of interest in the trade

papers and *THE CHRONICLE* of the establishing of a system of training for young gardeners in America.

It surely is an inspiring idea to see that the great majority of gardeners and superintendents are beginning to realize that some systematic method must be conducted in order to produce an efficient and practical force of new members of the Gardening profession here in America. Since the American youth does not desire to pursue a system of long apprenticeship, as is found in the Old Country, we must make it possible for him to obtain a similar knowledge and experience in a more attractive way. Hence, this establishment of a Training Course for Gardeners.

Through the excellent work and earnest efforts of the N. A. G., in conjunction with the Massachusetts Agricultural College, I believe there will be developed a system of training that will compare favorably with any in the European countries.

The young men who take this opportunity and carry this work through to a finish will never regret it, and especially that time spent at the State College at Amherst. Being a graduate of that fine institution, I fully realize the unlimited possibilities of such a course.

A theoretical knowledge alone can never make a young man a first-class gardener. But, with such knowledge, he can more readily and more efficiently acquire the practical experience that will be his opportunity to get under the careful guidance of the N. A. G. The work at the College will be most successful under the direction of Professor Waugh, and I am sure the co-operation of College and the Association will bring good results.

Such men as Mr. Craig and Mr. Cameron, whom I know personally, will help bring success to such a movement, and no doubt there are many others thoroughly interested in pushing the good cause along.

Trusting that there will be a good turnout of America's future gardeners, this coming Fall, I am,

E. STANLEY DUFFILL.

AMONG THE GARDENERS

Frank C. Slade, head gardener from 1911 to 1920 for C. W. Barron of Cohasset, Mass., died on July 29, after a sickness extending over two years. A native of Rockdale, England, he came to America in 1889, and had worked in Lowell and other cities as gardener before going to Cohasset. His son Frank succeeded him on his retirement at Cohasset. He was a genial man, a good gardener and had a great number of friends who mourn his passing. He was 65 years of age and leaves a widow and four children. Interment services were held at Cohasset on August 1.

Mr. and Mrs. Stanley Jordan of the Harkness Estate, Waterford, Conn., sailed on the *S. S. Aquitania* of the Cunard line August 1, to pass two months in England. Mr. Jordan plans to trot around to different parts of the British Isles, and to try and find out the real conditions and prospects of horticulture in general, particularly regarding the private estates.

We are sorry to have to announce the retirement of W. N. Craig from the professional field of gardening, to enter into the commercial field. Mr. Craig who is well and widely known throughout the country has resigned his position as superintendent of Faulkner Farm, Brookline, Mass., where he has been for the past ten years, and previous to that, superintendent of Langwater Farm, North Easton, Mass. Mr. Craig has bought a piece of ground in Weymouth, Mass., where he will engage in growing, specializing in hardy subjects. While Mr. Craig is about to leave the professional ranks for the commercial field, we are sure, however, that he will not lose his interest in the private gardeners' affairs.

Frank H. Ryan, formerly gardener on the late W. Harry Brown estate, Beverly, Mass., has taken the position of gardener to Gen. Edgar R. Champlin, Beverly Cove, Mass.

George A. Burnett of the firm of Burnett Brothers, New York City, is now in Europe. He sailed from New York on the *S. S. Adriatic* on July 22, accompanied by his wife and son, Samuel. His trip will include visits through the British Isles, Holland and France. Combining business with pleasure, Mr. Burnett intends calling on the leading seed and bulb growers in these countries. A pleasant feature of his trip will be a visit to scenes of his boyhood days in Ireland.

Luscious Strawberries

Fresh from the Picking

THEY add the crowning glory to the home garden plot—the final satisfaction to the perfect meal. Their culture is a pleasure—their flavor a delight.

Plant Them Now and Pick Your Own from

LOVETT'S POT-GROWN STRAWBERRY PLANTS

Each taken from an individual pot and shipped to you ready for setting out in your own garden. Selected from the superior stock of America's foremost berry culturists.

An attractive little book, No. 105, tells about the varieties, preparation of the ground and their culture. Mailed with pleasure on request.

J. T. LOVETT

Berry growers for Almost Half a Century

LOCAL SOCIETIES

NASSAU CO. HORT. SOCIETY

The regular monthly meeting of the above society was held in Pembroke Hall on July 10, with President Milstead occupying the chair. Two petitions for active membership were received at this meeting. President Milstead appointed A. Andrews, James McCarthy and Ben Southerland to judge the exhibits and their awards were as follows: 6 tomatoes, William Milstead, 1st; 25 string beans, Peter Stobie, 1st, Thomas Twigg, 2nd; 2 cucumbers, Thomas Twigg, Cultural Certificate; 8 vases snapdragons, William Milstead, honorable mention; 1 vase gladioli, Thomas Twigg, honorable mention; 3 vases gladioli, William Noonan, honorable mention.

William Noonan, the dahlia specialist, gave \$50 for the dahlia show. An essay on "Old Gardeners" was ably read by Thomas Twigg. The Nassau County Horticultural Society will meet on August 10. Exhibits for the August meeting, 6 ears of sweet corn, 1 outdoor melon, 12 mixed asters. Thomas Twigg, special 3 vases perennials, 1st prize \$3, 2nd prize \$2. A. S. Cook, Cor. Secy.

WESTCHESTER AND FAIRFIELD HORTICULTURAL SOCIETY

The monthly meeting of the above society was held in the Y. M. C. A. building, Greenwich, Conn., on Tuesday, July 11, a large number of members attending. There were several new members elected, and T. J. Bulpitt was elected corresponding secretary to succeed H. Jones, who resigned recently.

The committee selected to arrange the annual field day and dinner with the Tarrytown Horticultural Society reported that the combined societies will hold same at Roton Point, Conn., early in August.

About This Particular Greenhouse

IT happens that only yesterday we received from our publishers a rather delightful bit of printing called "Glass Gardens," in which a complete description is given, of an exact duplicate of this particular house.

The view point is a bit different, but the plan is the same.

As companions, are four other houses of simpler design and lesser size.

Send for this new Glass Garden Circular.

Or if you prefer, send for one of us to come and talk over greenhouse possessing with you.

HORT. SOCIETY OF NEW YORK

The annual gladiolus exhibition of the above society in co-operation with the New York Botanical Garden, will be held in the Museum Building, New York Botanical Garden, Bronx Park, New York City, on Aug. 19-20, 1922.

The prize list for this year has been very much enlarged, and will include prizes for almost any variety of exhibits. Special prizes have been offered for both the ordinary and the Primulinus types, for displays arranged for effect, dinner table decorations, vases, baskets, etc.

Garden clubs are especially invited to compete, and will have classes open only to them.

Luncheon will be served to all exhibitors, and every facility placed at their disposal. Those who are unable to come in person may send their exhibits by express prepaid to the Museum Building, where they will be taken care of and staged.

The schedule of prizes is now ready, and may be had on application to the secretary of the exhibition committee, Mrs. George V. Nash, New York Botanical Garden, Bronx Park, New York City.

CITY GARDENS CLUB OF NEW YORK CITY, INC.

The City Gardens Club of New York has planned a photographic competition to stimulate interest in beautifying New York City. We felt that you would be interested in furthering such a laudable scheme, and so we are pleased to submit the plan (reverse side)

CONINE NURSERY CO.

East Main St. Stratford, Conn.

Established 1865 Reference Dun

IN LARGE SIZES OF

Hemlock, Biotas, Pines, Retinosporas, Blue and White Spruce. We have the BEST stock in the UNITED STATES.

We also have a good assortment of General Nursery Stock

WANTED: A NURSERY

A Gentleman, owning a thousand acre place within one hundred miles north of New York City, interested in perennials, rock plants, trees, shrubs, native flowers and shrubs, etc., is willing to give land, house, and half capital to an established firm of nurserymen, or member of such firm, willing to locate nursery or branch on partnership basis on his place. Write full details, in strict confidence, to SIRMIO, care of Gardeners' Chronicle.

and trust that it will be possible for you to join us in this effort.

The object of the club is to turn unsightly backyards into gardens, to beautify all waste places, to plant trees near important buildings and along treeless streets, to encourage window-box planting, and to be observant of the workings of the park department, in order that we may make city life richer by fostering the love of beauty.

In order to carry out these important ideas, we feel that it is very necessary to have photographs of successful developments, so that people can clearly see the possibilities of their own backyards, and receive inspiration. This is the primary reason for competition, to secure pictures to carry on the good work of making New York a better place in which to live.

May we hope for your cooperation in this work?
FRANCIS B. JOHNSON.

Here and There**WILD FLOWERS BEING EXTERMINATED**

The beautiful wild flowers that once adorned our roadsides, meadows and woods are rapidly disappearing, especially in the country around big cities, and the reason, according to Albert A. Hansen, who sends to Science an earnest plea for their preservation, is the "unrestricted, indiscriminate, thoughtless pickings to which these beautiful plants are subjected. Each spring witness the descent of legions of thoughtless flower-gatherers who ravish the flora with a thought that the tearing away of flowers robs most plants of their only method of reproduction.

The remedy is not the prohibition of wild-flower picking, but the care of pickers not to gather too many. "Sufficient," says Mr. Hansen, "should always be allowed to remain, particularly in the case of annuals, to produce seed and so perpetuate the species. Plants should never be gathered by the roots, as is so frequently the case with hepatica, and many other plants. Plants grow

**To Have It Then, You Must Build Now**

As magically as greenhouse flowers seem to grow, still there is a good deal of plain every day common sense about it.

You do have a complete control over conditions and can force things faster than is their usual wont.

But even so, what you gain in time by forcing, you just as surely lose in quality.

Time, therefore, is the vital factor which prompts us to urge you to build your greenhouse now if you expect to surely have joy giving blooms in abundance for Thanksgiving, and all the coming fall and winter through.

Fortunately, greenhouse building the way we do it is carried on with rather surprising speed and quite devoid of the usual bothersome.

To help you in selecting just the house best adapted to your purposes, we have a delightful booklet called "Owning Your Own Greenhouse." Send for a copy.

ing from long, creeping stems, as arbutus and ground pine, should never be torn out.

"It is especially desirable that plants such as the wintergreen be allowed to mature fruit as food for birds during the harsh winter months. Without this source of food many birds die of winter starvation. It is desirable that the picking of such weedy but attractive plants as daisies, buttercups, golden rod and asters be encouraged, since by so doing no harm results and the farmer is assisted with his weed problem. In addition, the cultivation of wild plants in our gardens may save many species for the enjoyment of future generations."—From the *New York World*.

A Transformation

A Scotchman who landed in Canada not long ago accosted a coal black negro for a direction. It happened that the black had been born in the Highland district of Scotland and lived there most of his life. "Hey, mannie," said the Scotchman, "can ye nae tell me whaur I'll find the kirk?" The darkey pointed with his arm. "Go right up to yon wee hoose and turn to ye're right and gang up the hill," said he. The visiting Scotty looked at him in horror. "And ar ye frae Scotland, mon?" he asked. "R-right ye arre," said the darkey. "Aberdeen's ma hame." "And hoo lang hae ye been here?" asked the Scotchman breathlessly. "About two year," said the darkey. "Lord save us and preserve us," said the new arrival. "Whaur ken I get the boat for Edinburo?"—*Argonaut*.

On A Modern Steamship

The other day a great liner, equipped with all the modern necessities, including a palm court, well filled with the varied blooms that spring up in the Atlantic field, set out on her voyage to New York. The captain, ascending a gangway, met a venerable but unknown figure wearing the company's cap and uniform. "Are you of the ship's company, my man?" "I am, sir." "What is your rating?" pursued the astonished skipper. "Please, sir, I'm the ship's gardener," was the reply.—*The Nation and the Athenaeum*.

WILSON'S O. K. Plant Spray

Kills Plant Insects, Scale and Mildew

Used by Leading Gardeners

**Bbls. \$90; ½ bbls. \$50; 10 gals. \$20
5 gals. \$10**

Brooklake Park,
Madison, N. J.,
July 14, 1922.

Andrew Wilson, Inc.,
Springfield, N. J.
Gentlemen:

Your O. K. Plant Spray as its name implies is super-excellent. It is more than you claim for it. Outdoors we have cleaned our conifers of red spider. Rose garden is free and no dreaded rose beetle to dismay our efforts. Indoors I was at first skeptical with its application upon orchids. Previously I never sprayed them without loss of fleshy roots, no matter how light the application, but your spray has cleared all doubt as to its safety on rare orchids.

Carnations and Mums are kept free of pests and fungus disease. Its two-fold use is wonderful. Roses, our situation favors black spot, and every fungus disease a rose is heir to, but we spray the soil of the benches every week with 25% solution and are free.

It is in short an allied army of protection and care of all plants in horticulture's realm. I heartily recommend it.

Yours very truly,

Supt. of Howard Cole Estate, W. R. Fowkes.

SPRAYING

is as

Essential as Fertilizing

Successful cultivation demands a knowledge of the habits of plant insects and diseases, and the proper remedies for their control.

APHINE, an effective remedy against all sap sucking insects infesting flowers, fruits and vegetables, is free of the disagreeable odors and features of most insecticides. It invigorates plant life and is unexcelled as a wash for decorative plants. Aphine will not injure the most tender flower or foliage.

FUNGINE is an excellent remedy for mildew, rust, and other blights. It is readily soluble in water and contains no sediment. Fungine does not stain the foliage but cleanses it.

VERMINE is a soil sterilizer and vermicide. It destroys cut, wire, eel and grub worms, maggots, root lice and ants, and will protect your gardens and lawns from ravages under the soil.

There is but one convincing way for you to become familiar with the merits of these products and that is to try them out for yourself. It will prove worth while.

Sold by dealers in various sizes.

"Coolkenny," the home of Dr. and Mrs. J. Leslie Davis, Haverford, Pa.

"A marked improvement in one year"

An unsolicited letter from Dr. J. Leslie Davis, Haverford, Pa.

The Davey Tree Expert Company, Kent, Ohio.

Dear Sirs:

It is a pleasure to testify to the very satisfactory work that has been done by the Davey Tree Surgeons at "Coolkenny," especially where it was not without some misgivings that the first contract was signed for them to undertake the treatment of quite a number of active decay processes in some of the most valuable trees on the estate two years ago.

The clause in your contract stating that your men would retire from the operation any hour the work did not progress satisfactorily, however, was reassuring, and the degree of satisfaction can best be judged by the fact that three men were permitted to work two weeks

last year and four men for another week this year.

The clearly perceptible improvement in one year's time of all trees that were treated is most convincing that the men you sent to us were truly scientific and expert in every phase of their profession.

(Signed) J. Leslie Davis

Every gardener and estate superintendent has a most important work in the saving of trees under his care.

Davey Tree Surgery brings to his aid the highest development of science plus a generation of experience. A careful examination of your trees will be made by appointment.

HIGH QUALITY Bulbs · Seeds · Plants FOR AUTUMN PLANTING

This is the title of our Autumn Catalogue which we have been mailing to our patrons during the month of September.

If your name is not on our mailing list, write to us and we will send you a copy of this Catalogue at once.

For the past **twenty-five years** we have been supplying an increasing number of particular flower lovers with our Seeds, Bulbs and many of their garden needs.

HIGH QUALITY BULBS WHY WE USE THE EXPRESSION AND HOW WE ENDEAVOR TO MAINTAIN IT

High Quality Bulbs are bulbs of proper flowering age, grown in a careful manner; thoroughly ripened and cured; and selected for size. The bulbs listed in our Autumn Catalogue are grown in Bermuda, California, Japan, France, but principally in Holland. We contract with growers only for each variety listed. No grower in Holland, for example, grows all the varieties of Dutch bulbs offered by us. Therefore, we place advance contracts for the various varieties with specialists. The bulbs are carefully packed and shipped to us in the autumn.

On their arrival in New York they are immediately unpacked so as to avoid becoming "heated" and carefully arranged in our own building, examined and passed on by thoroughly trained men.

Things and Thoughts of the Garden

WILLIAM N. CRAIG

LIBRARY
NEW YORK
BOTANICAL
GARDEN

THERE is a great paucity of flowering shrubs which bloom in August and September. It is true that berried plants are numerous and very beautiful, but flowers are far from abundant. The Indigoferas are not much grown, perhaps because they are not much known and rarely offered for sale, and for the further reason that they do not make as "stunning a show" as some other shrubs. There are said to be about 330 species of Indigoferas, mostly tropical, although several are native to the United States. The indigo of commerce mainly comes from *I. tinctoria*, an Asiatic specie and *I. anil* from the West Indies. At one time the last named specie was much grown commercially in North Carolina, as much as a million pounds being produced in 1775. The rising importance of the cotton crop eventually drove indigo to the wall, but even today plants which are escapes from cultivation, are often found.

* * *

While most of the Indigoferas are greenhouse plants, one or two of comparatively recent introduction from China are hardy as far north as Boston and prove good garden plants. *I. amblyantha* from Western China makes a neat and graceful shrub, 5 and 6 feet in height, carrying in late August numerous dense racemes 3 to 4 inches long of pink flowers, the blooming period extending until October. *I. decora alba* is a low growing almost prostrate plant, hardy at the Arnold Arboretum, and in late August was carrying quantities of its lovely pure white racemes. A charming species is *I. kirilowii* native to northern China and Korea and introduced 10 years ago. The racemes produced in August and September are bright rosy pink in color and resemble *Robinia pseudacacia* in color, and they are produced in great abundance. The plant is of moderate height and of graceful habit and should have a place in every garden where flowering shrubs are valued. The Indigoferas propagate readily from cuttings and layers. *I. amblyantha* produces seeds in abundance, but *I. kirilowii* carries none at all. All can also be propagated by division.

* * *

The hydrangeas while about all of one color, white, are most useful in late Summer, but it is unfortunate that the excellent garden species *H. paniculata grandiflora* is so distressingly overplanted. It seems as if every one with a garden, no matter how small feels it a necessity to plant one or more of this variety. It is a pity more of *H. paniculata* is not grown as it is much more graceful than

its more showy sub-species, *grandiflora*. The sub-species *præcox* is very distinct both in foliage and flower and while blooming earlier than the other forms is still in good condition at the end of August. *H. radiata* has handsome leathery foliage and large circular cymes of flowers, the outer row of flowers being sterile. This is a fine species, better than the variety *cinera* which is more planted. *H. Sargentiana* makes a very handsome shrub; the nearly flat dense cymes are 6 inches or more across, the fertile flowers pale violet, and the sterile ones pure white. It is a most beautiful shrub from Central China, but unfortunately not hardy in the north, and it also requires shade. Speaking of hydrangeas, I have been surprised to note how hardy the new French race of *Hortensis* hybrids have proved. At the Blue Hill Nurseries, South Braintree, Mass., large clumps have passed through several severe Winters unprotected and flower freely each year.

* * *

There have been some beautiful introductions among the Cotoneasters in late years, mainly from Western China. The varieties are so numerous as to be almost bewildering. Some of us remember *C. Simonsii* as a climber in Great Britain and still have vivid recollections of the glorious masses of scarlet fruit it carried. In Massachusetts this species will not winter, being native to the Himalayas, but many others prove very hardy. A few specially desirable sorts are: *C. hupehensis* which makes a dense and very wide spreading shrub, 8 to 10 feet in height, and its pure white flowers are followed by great quantities of brilliant subglobose fruits. This is a beautiful plant whether in flower or fruit, but it must have ample space to develop. *C. tenuipes* attains a height of 5 to 6 feet and is wide spreading. The rather large oval black fruits are abundantly produced and are very handsome in August and onwards. *C. adpressa* is of prostrate habit and carries scarlet subglobose fruit. *H. horizontalis* of which there are a number of forms is probably the most valued of the Cotoneasters. It makes a rather low but wide spreading shrub with round-oval foliage and bright red fruits which are produced in great abundance. The form *perpusilla* is probably the finest of all species for the rock garden, while it rarely exceeds 2 feet in height, it spreads 10 to 15 feet across and the bright shiny leaves, which are smaller than in the type are handsome even without the great number of brilliant fruits.

OCT 9 1922

C. horizontalis Wilsoni is distinct in habit but grows more erect, is more stiff in habit and not so desirable as some others. *C. Dielsiana* produces slender spreading and arching branches and grows 6 to 7 feet in height, and the red fruit are carried in bunches like *Crataegus*. This is one of the very best species. A very pretty low growing and dense shrub is *C. apiculata*, and the leaves are nearly circular and the fruit scarlet. It makes a charming rockery plant. *C. racemiflora soongarica* grows 8 to 10 feet high and 12 or more feet across. The foliage is rather scant, but the great numbers of brick red fruit which cover every stem make the plant a striking object in Fall. The fruits resemble *berberis* in color and persist for a long period. *C. multiflora calocarpa* is a rather thin growing shrub of vigorous habit, carrying large numbers of dark cherry-like fruit. The foregoing are some of the more striking cotoneasters. For the shrubbery and the rock garden they are unexcelled, charming in flower, beautiful in fruit, free from insect pests and with, in nearly every case, bright shiny foliage, they should be in every garden worthy of the name. Propagation by seeds and layers is easy with all species.

* * *

The aconitums or monkshoods are beautiful plants in the hardy garden. Many of us are able to grow them but indifferently. Being native, as they are to mountain regions in Europe, temperate Asia and North America, they succeed less satisfactorily in the warmer and drier plains. Any one who has visited such northern summer resorts as Bar Harbor or any of the islands along the coast of Maine must have been struck by the wonderful luxuriance of the monkshoods. They are to be seen in every garden and often 8 to 9 feet in height. In fact, they increase so rapidly that I have seen them running practically wild on Mount Desert Island. Only a few varieties of aconitums are grown in America compared with Europe. *A. Napellus* and its varieties are the most prominent, while *A. autumnale*, *A. Fischeri* and its variety *Wilsoni* are of the greatest value in the garden.

A. Napellus is the most poisonous species and is largely grown in Europe for the official mite, and the leaves also have medicinal value. Several other species are grown in China, India and Japan for poisonous alkaloids. The variety *Wilsoni* which is a tall grower is most useful in the garden in Fall, coming in as it does, when the second crop of delphiniums have passed and good blue flowers are scarce. Transplanting is best done in the Fall, and it will be found that if given a little shade aconitums do much better.

* * *

The days of specimen stove and greenhouse plants seem to have passed. Years ago we marvelled at the wonderful plants of allamandas, dipladenias, Bougainvilleas, ixoras, *Stephanotis*, ericas, Francisceas, Rondeletias, statics, and others. Large sized plants of some of these are still seen but both here and abroad classes are now seldom allotted to them. For many years that noted grower, Cypher of Cheltenham, produced marvellous examples of cultural skill at the great British provincial shows like York, Wolverhampton, Shrewsbury and Birmingham. The great war with the scarcity of coal and labor caused the virtual wiping out of these grand specimens, and in their stead have come classes for medium sized plants and groups, the latter being a great feature at all the large British Summer and Autumn shows. Our hot climate makes it impossible to duplicate under canvas such exhibitions, and we are mainly dependent on Spring and Fall shows, except for special shows of such popular plants as peonies, *gladioli* and dahlias. I can imagine

nothing more charming than a great flower show under canvas in well ventilated tents where the sun is not too broiling. I have attended one or two shows here in tents which were small but delightful. On the other hand, some held under our August broiling sun bring back memories of wilted judges, wilted exhibits, and a perspiring public.

*

The days when we used to hear the pedlers cry, "Fine ripe strawberries, three boxes a quarter," have passed, never perhaps to return, but the cry combined as it is with the profusion of bright scarlet berries with their fragrances, produced on even the casual passerby a fascination created by few if any of the other fruits which later in the season find places on our tables. Can anything be more alluring than a basket of fresh picked, well ripened strawberries, resting on some of their own foliage? With the dew still sparkling on their glossy sides and flanked by a generous supply of rich cream, truly 'tis a "feast for the gods." Strawberries have been in cultivation a long time. Historical mention is made of the fruit as far back as the 13th century, but no record of their cultivation is made until 1483. In June of that year Richard, Duke of Gloucester, is reputed to have said that he had seen good strawberries growing in the Bishop of Ely's garden. The strawberry of that day and for several centuries later was simply a wild plant transferred from hedgerow to garden. Not until the introduction of the large Chilian strawberry in the last years of the 18th century did a new era in strawberry culture begin, aided by the addition of new species notably one from North America.

* * *

A tribute must be paid to the skillful hybridizers here and abroad who have helped to evolve the strawberry of today. In the nature of things new varieties must constantly appear or degeneracy would result. The only way to keep up or improve the standard of existing varieties is to save new seedlings. The number of new seedlings introduced in America must run into the thousands, and a few of these have survived more than one generation. The old Gandy is still popular and with many Brandywine is equally good, so is Sharpless.

* * *

The finest all round variety introduced since I came to America is Marshall, picked up by chance a wildling at Marshfield, one of the strawberry centers of Massachusetts. Sent out 30 years ago, this variety has never been surpassed for color, size, flavor and all round excellence. For forcing purposes it remains without any serious rival. It needs, however, a stiff, rich, retentive clay loam and liberal manuring to do its best outdoors. It is worthy of note that since the introduction of Marshall at every strawberry show held in Boston in all that time this variety has won "hands down" for the best dish of strawberries. The everbearing race of strawberries prolongs the season very nicely. Superb and Lucky Boy are my choice of this section. Our American strawberries are much more acid than the European ones. What we need now more than anything else is varieties as sweet as Royal Sovereign and Laxton's Noble so that we can dispense with sugar when eating them and rely on cream only.

* * *

It is interesting to note that everlasting flowers of various kinds, such as *Rhodanthes*, *Acrocliniums*, *Helichrysums*, *Gomphrenas* and *Staticas* are finding increasing favor among flower buyers as well as owners of home gardens. They have sold satisfactorily in the flower

Rambling Remarks on Plants

FLORUM AMATOR

THE bunches of berries on the *Viburnum Opulus Americanum*, commonly called Cranberry Bush or High Cranberry, which began to turn red in the last of July, have now put on a bright scarlet color. Retaining this color they will remain on the bush, to which they cling tenaciously, all Winter, for the birds do not eat them. Their acid fruit is a substitute for Cranberries, hence their name. This shrub is a native from New Brunswick far westward and south to Pennsylvania. In a Winter garden of bright berried shrubs this *Viburnum* is almost unsurpassed. The variety, *Sterile*, of *V. opulus*, the European Cranberry Bush, is the well-known Guelder Rose or Snowball, while *V. tomentosum plenum*, is the beautiful Japanese Snowball. Several of the *Viburnums*, of which there are about 120 species widely distributed through the different countries of the world, are among the most desirable of shrubs in ornamental horticulture. The Roman poet, Virgil, immortalized, so to speak, the *Viburnum* in a famous simile in his first eclogue, in which he says:

“Verum haec tantum alias inter caput extulit urbes,
Quantum lenta solent inter Viburna Cupressi.”

a prose translation of which is as follows:

“This (city, Rome) has raised up her head as high among the other cities as the Cypresses have raised theirs among the supple *Viburnums*.”

Spiraea Bumalda, variety “Anthony Waterer,” is one of the most desirable of all pink or crimson Summer flowering *Spiræas*, for the *Spiræas* we may note are divided into two general seasonal classes, namely, Spring and Summer bloomers, the flowers of most of the former being white and of most of the latter pink or crimson. The Spring bloomers give in general but one crop of flowers, but some of the Summer bloomers several crops. Anthony Waterer, if all the dry flowers or seed pods are cut off, and each branch is cut back a few inches, will give a moderate crop of pretty Autumn blooms, and furthermore, the new foliage which this shrub will put on after its pruning will have a variegation of pink, white and green, the same as the new foliage has in early Spring. Of all the strictly deciduous shrubs there is no one better to use in making a low hedge, for it bears pruning well in any season, and is among the hardiest and most floriferous of shrubs, and nearest immune from disease or insect attacks. There is a native *Spiræa*, namely *S. tomentosa*, commonly called Hardhack and Steeplebush, whose steeple-shaped panicles of pink flowers appear from July through September, and whose leaves beneath are densely grayish or yellowish tomentose. This is an upright grower reaching a height of about four feet. We have always wondered why we have not seen this *Spiræa* used in forming a hedge. The plants would, we think, if cut down to the ground each Autumn, grow rapidly on the coming of Spring, and form an attractive hedge, producing flowers on the new wood.

There is a species of *Potentilla*, Cinquefoil, Five-Finger, a native of North America, which is an unique shrub, namely, *Potentilla fruticosa*. This shrub reaches an extreme height of about four feet. It prefers a moist position. We well remember the first specimen which we ever saw, in full bloom growing in a moist swamp way back in those happy days when we spent much time in field botany searching for specimens new to us. This plant, however, like the *Hibiscus moscheutos*, and some other swamp plants, will grow in a dry position also. We have

spoken of this as an unique shrub, and we think a brief description of it will uphold our statement. Though growing only one to four feet high, it is shrubby and much branched; its bark is oddly shredded, the leaves are pinnate with five to seven leaflets with revolute margins, and silky, giving to the bush a very odd appearance which immediately attracts attention; its flowers are bright yellow, numerous and showy, and appear throughout the Summer. This shrub, too, we think, would make a pretty and unusual low hedge. One tires a little, though they are very appropriate we admit, of the ubiquitous Privet and Barberry in hedges.

We often speak of persons as sensitive, we meet them on every hand. We have sensitive plants also, not a few of them indigenous. Growing in the sandy field and roadsides from New England to Florida and west to Indiana, Kansas and Louisiana we find *Cassia nictitans*, Wild Sensitive Plant, the ten to twenty leaflets of whose pinnate foliage will fold up, if brushed gently by the hand. To this genus by the way, belongs *Senna*, whose leaves are used in medicine, namely *S. acutifolia* of Egypt, and *S. angustifolia* of India and also our native Wild *Senna*, *S. Marilandica*.

The twice pinnate leaves of our native *Schrankia uncinata*, Sensitive Brier, a plant which, by the way, has recurved prickles, hence its specific name *uncinata*, and round heads of rose-colored flowers, are very sensitive. This plant is found from Virginia to Florida and westward to Illinois, Kansas and Texas growing in dry sandy soil, and is nearly related to the true Sensitive Plant, *Mimosa pudica*.

Mimosa pudica is not strictly indigenous in this country, but though a native of Brazil, is widely naturalized in warm countries and has run wild in our Gulf States. This somewhat shrubby, hairy, spiny, erect, branching plant, is very sensitive; when its pinnate leaves are touched, the petioles fall and the leaflets close, especially on young plants.

The stamens of our Common Barberry, *Berberis vulgaris*, flowers are very irritable when touched, as is well known to the boys and girls of New England, where this shrub grows, and spring out of the concave petals in which normally they rest, in towards the center of the flowers.

There are two old vegetables which when we were boys, we used to see growing in many of the kitchen gardens of New England, generally close to the garden fence, where it would not be necessary to disturb them in the Spring plowing or spading, for these plants are perennials. The one is *Levisticum officinale*, Lovage. This is a tall plant with dark green shining wedge-shaped leaves, cut toward the apex, its radical leaves being two to three times divided. The leaf-stalks used to be blanched and eaten like celery. Lovage is a native of Southern Europe, but has escaped from cultivation in some places in North America. Lovage may be set out in beds about three feet apart each way. The plants when well established will be profitable for several years with little cultivation. The second of these two old vegetable plants is *Crambe maritima*, commonly called Sea-Kale. This is a smooth, strong growing perennial about two feet high, whose heavy, large leaves are cut and somewhat curled or fringed; it is a native of the coasts of Europe. This plant is worth cultivating.

Autumn Glory at Englishton Park

HELEN ORR ENGLISH

RETURNING to the country late in the Autumn after an enforced stay during a large part of the Summer in a town apartment has the same effect upon me as when I receive the first Spring flowers from my garden after a long, cold, dreary Winter in town. The unutterable joy of returning to find the house overflowing with

An excellent view of the rock garden at Englishton Park.

the results of years of past study to see that it has been kept in one's absence the same as when present, grounds and home perfect in their Autumn glory, a tribute to gardener and housekeeper. I cannot but speak of the faithful caretaker of this particular home, whose daily pleasure it is to concoct, if one may use such a word in horticulture, such lovely arrangements for my enjoyment. Years ago I remember so well her bringing me in from the northern wood a handful of wonderful, odd, and unusual berries and leaves. It was not familiar to me but after a little searching among my books, to my joy I found it to be the bluest berried plant, whether wild or cultivated, that grows, and which I had never seen but had read so much about, *Clintonia borealis*.

After this little digression, I shall now write of the things which give me so much delight, for I am longing to tell those who love Nature of the beauties awaiting me both in and out of doors. A return at that time of the year to the lover of the all year round garden is an inspiration for future work, and I am filled with a desire to imbue others with my love of gardening and to impart any knowledge I may have gleaned from years of experience. I never really know what to plant for Fall effect until I see the beautiful flowers, branches of trees and berried shrubs that I can have in late October and November, many of which will remain during the Winter to cheer the gloomy days. The little known Autumn crocus, *Colchicum autumnale*, continues to bloom late in its somewhat desolate surroundings of Virginia Willow (*Itea virginica*), which have yielded of their glory for weeks in the preceding May and June. This late straggler makes me think of the Indian Pipe (*Monotropa uniflora*), which I have seen by the hundreds growing out of rotted trees and leaf mold in the dense woods of Michigan, a little ghost-

like flower, and without odor. For the first time, when I saw the mass of crocus at my feet, I unconsciously connected the two. The Spanish Bayone or *Yucca*, "Our Lord's Candles," of a very different family and far from being a fungus or parasitic growth, as the Indian Pipe is properly classed, has that same deathlike, odorless whiteness. I do not know why I associate these three different plants—one a bulb, one a fungus growth, and the last a native of hot desert sandy lands, transplanted to our gardens, but there must be a similarity for me to do so.

The wonderfully colored leaves of the "Winged Strawberry" (*Euonymus alatus*), and its cork wood branches make a fine showing as a background for the lily pond several hundred feet away from the house. In the garden this group immediately attracts the eye and holds it; while indoors, when mixed with the dainty, feathery sprays of *Spiraea Thunbergii*, the "Winged Strawberry" is attractive beyond words. It is just as lovely when combined with the stout stiff branches of the dark green Mountain Pine. *Spiraea Thunbergii* planted out of doors with *Kerria japonica*, single *Corchorus*, is a combination no garden should be without if only for the Fall effect and contrast of the two during the entire Winter. The red leaves of *Rhus aromatica* (Aromatic Sumac), rivals the *Euonymus* and I for one would not be without this especial variety.

The huge beds of annual scarlet sage are brilliant in August and September. It is so common and deplorably overdone and over-rated in the cities that I plant it very sparingly and then only for the pleasure that the brilliant mass gives to passers-by. Its short lived beauty passes entirely at the touch of the first early frost and becomes just a brown dead mass. Why will not the masses appreciate the pleasures to be derived from hardy gardening?

The path leads to the right, beyond is a ring, curled willow (*Salix auriculata*), an oddity.

The home attests to the hardiness of my garden. It glows with the scarlets and golds and greens of the varied plantings whose beauty I shall attempt in a feeble way to picture to my readers.

Different from the arrangement of *Euonymus* and dwarf Swiss Mountain Pine mentioned above, and as

effective, are the trailing junipers, the Japanese, *squamata* variety are preferable, mixed with the bright red of the Winter berry, the deciduous holly. In the garden, whether as specimen or as groups, the effect is gorgeous, and I have a little pre-Christmas display in October.

For indoor decoration the English Yew, *Taxus baccata*, is unusual when combined with Japanese anemones, both single white and the semi-double "Whirlwind." These Japanese anemones are most difficult of cultivation for me and I have known these rare beautiful plants to change their position in the same bed. I have planted them in one place and in the Spring have found that they chose to come up closer to the stone foundation than I had intended. When this unique idiosyncrasy occurs and they refuse to stay "put," it is necessary to use other plants to edge the bed, perhaps the delightful blue campanulas or Japanese bellflowers, which follow the Poet's Narcissi blooming in early Spring. The anemones require proper soil, mostly wooded earth or leafmold, and a shady location. Their natural tendency is to hug the stones wherever possible.

Can you visualize a scarlet cactus dahlia or two in a vase with a clump of rugged white Japanese rose, the justly well known *Rosa rugosa*? Also another grouping of an old fashioned "Show" rose-pink dahlia, an Ulrich Brunner rose and a Conrad F. Meyer rose (*Rosa rugosa*)—without question the most beautiful Japanese rose grown—in a glass vase with a spray of the delicious feathery, silvery-blue *Retinospora squarrosa*?

A few hardy delphiniums as well as the aconitums, or Monkshood, still bloom on my return late in the Fall, and furnish lovely blooms for the house. I always look upon these two as closely related because to me they seem somewhat alike. I find also at that time a few *Chrysanthemum arcticum* or daisies, and mixed with the purple of the delphiniums they make a splendid display.

A large bowl of African marigolds illuminates the dining room and in a wall cabinet under a brilliant inside light, in a peculiar scarlet vase, I place a few sprays of the scarlet and gold berries of the *Euonymus*, with some cuttings of the English Yews, the *repandens* variety. A little later the wall pockets on each side of this cabinet are filled with bronze chrysanthemums, the dear old pungent sort that, to my taste, is the only real chrysanthemum.

I have a more delicate arrangement of the *Tartaricum* variety of hardy asters, China asters and *Spiraea* sprays with a few black berries of the Regal's Privet, which, strange to say, notwithstanding the many colors, all blend well under low lights. So many vases and bowls of Winter berries, *Ilex verticillata*, give me a Christmas feeling in Indian Summer days. I am the very proud possessor of a few American holly bushes that are old enough to yield their genuine holly berries, and these are especially treasured because I do not know of any other holly bushes in Indiana. There are so many pseudo-holly leaved shrubs that one more deeply appreciates the real when fortunate enough to have them.

The long borders of nasturtiums are in all their glory and the fragrance indoors is very sweet. They are most pleasing when placed with rare golden Chinese cypress or *Arbor vita* and the biotas, which are planted in my garden at the end of the nasturtium borders. This reminds me to caution any one when buying seeds to buy only the choicest in the Spring, as one is well repaid for extra expense, if any. In dealing with the practical end of gardening, I always consider Spring the better time to plant the late flowering or berrying plants and shrubs about which I am writing. It seems the more logical time for success with them, as they appear to be more dormant than when they are yielding their glory in the Autumn.

The *Scabiosa*, or Mourning Bride, as well as nasturtium, repays one when only the best seed is selected, the choicest seed yielding the rarest shadings in these particular flowers. The same is true of dozens of annuals. As a result of my care in the Spring, I have a splendid planting all Summer of Mourning Bride, where they bloom every year as fillers for the Spanish Iris at the lily pond when the iris have bloomed and gone. The *Scabiosa* or Grand Mother's Pin Cushion, is such a clean and lovely little tufted plant, which frequently seeds itself in my climate, that everyone should have it. I cut it with abelias, sometimes called the arbutus shrub, another beautiful but little known shrub, and their purple and delicate pink shades harmonize so well together that one seems the complement of the other. I wonder who knows the unusual Beauty Fruit or *Callicarpa purpurca*, which is at its best in the late Autumn with its beauteous mulberry purple berries. The flower is so infinitesimal as to be unnoticed in the Spring,

Spiraea Thunbergii and *Corchorus Japonica* in bloom at Engliston Park.

but one is amply rewarded during the Fall months, when the shrub is heavily laden with delicately colored purple berries. The effect of half a dozen full bearing branches of their dry brown leaves mingling with a lavender phlox, a few hardy asters and leaves of *Thalia dealbata*, a semi-aquatic, is most unusual and striking.

Even the form gives of its beauty to my eye for color. In passing by a tobacco field a solitary bloom on a sucker of a tobacco plant attracted my attention. It is a most delicate shade of pink, a faint rosy dawn and it goes well with a very pretty black eyed, light blue delphinium, Kelway's "Silver Buckle." The combination is extremely delicate in coloring.

The cosmos in late Autumn are still lovely where protected from frost by the plantings. A single bloom of the lovely blue *Stokesia* with much of its crisp, green foliage, is a charming companion for a canary yellow dahlia. The blue and yellow were exquisite in a Rookwood green vase. Bowls of Polyantha roses, the Baby Rambler, and little Marie Pavie, throughout the house in full flower and bud make one think it is June instead of Autumn.

I cannot pass by some gorgeous trees without a word, the handsome sweet gums which enrich our gardens with their purple, dull red and green colorings; the variegated

(Continued on page 259)

The Greenhouse, Month to Month

GEORGE F. STEWART

WE are now well into what is termed the Indian Summer. After the first light frosts, we are sure to have a spell of warm weather and the greenhouse man is tempted to leave the more hardy plants outdoors for a little while longer. It is, however, safest to take no chances. Get everything into Winter quarters as quickly as possible. A friend of mine took the risk of leaving his azaleas out late one year and an unexpectedly sharp frost dropped all the buds, losing a whole season's effort for him. Last September and early October are very busy months. There are so many little things that are likely to be overlooked, especially if one is shorthanded, as many are.

Azaleas that are required by the first of the year should be placed in a cool light house near the glass. Syringing should be avoided as it is likely to start growth which may throw the flower bud. Should any young growths appear, pick them off as soon as they can be handled. The succession azalea plants are better in a cool pit from which frost is kept and which is not too light. In a structure of this kind they may be had in flower up to June if one has the later flowering varieties. They need careful watering, never being allowed to get dry. Occasional waterings with soft coal soot water, we find, keeps a rich color on the foliage and is not likely to stimulate growth if they are kept cool.

Similar treatment, we find, is good for acacias until they are wanted to come in flower when they must be given all the light possible, but never attempt to force with heat, as it will cause a loss of flower buds and start a new growth. Heaths and all other cool greenhouse hardwood plants may also be stored in a cool pit and when wanted in flower a light cool greenhouse is the place for them. Get all these plants under cover before the end of the month of September.

Bouvardias need an intermediate temperature and plenty of light to develop their flowers. If well rooted in their flowering pots a little stimulating with Clay's fertilizer once a week will help them. All *Buddleia asiatica* and *stevias* may be stored in the cool pit and removed to the cool greenhouse as needed.

Chrysanthemums are now at an interesting period and need liberal feeding to swell the flower buds. All watering is better if done in the forenoon. Have a nice dry bracing atmosphere over night. Close the bottom ventilators on cool nights. It will help to prevent mildew. Light dustings of air slacked lime under the foliage is very helpful in drying up any moisture that may be around. Disbud as soon as the buds can be handled. Train the specimen bush plants into shape as soon as they set bud. Put in cuttings of the Paris daisy (*Chrysanthemum frutescens*) for they will make nice plants by Spring and are useful also for cutting. Another beautiful and quaint flowering plant is *Statice Suworowii*. It is an annual and seeds sown now will make nice plants in six-inch pots by Spring. The variety *alba* in pure white will prove effective when grouped with other colors of plants.

Fuchsias that were rooted in August ought now to be ready for three-and-a-half-inch pots. If good specimens are wanted in nine and ten-inch pots next May, keep them moving along without getting pot bound. Train up the stems to a stake and at every five or six joints

pinch it and then take the strongest break for the leader. Take the points out of the side breaks every time they make three or four double leaves. This will fill in the sides of the plant nicely.

If good strong plants of the Lorraine type of *Begonia* are wanted, they can now be transferred to a cool house and hung well up to the light. By this treatment they will last longer than if transferred to a room when in flower.

Any nerines that are overcrowded in their pots may be given a shift but never pot them if there is plenty of water space in the pots. Immediately after flowering is the best time to pot them. These beautiful plants ought to be seen around greenhouses in the Fall of the year more frequently than they are. They flower at a season when flowers are none too plentiful and there is now quite a range of color among them. When grouped with adiantum ferns they are very effective.

Keep an eye on the calceolaria plants and pot them along if large specimens are desired next Spring.

Primulas may soon be shifted into their flowering pots. Pot all bulbs as soon as they arrive. They may be stored in any frost proof building and covered with sand to prevent the bulbs rising out of the receptacle as they are apt to do, if no pressure is on top of them. Frost will not hurt them but it may crack the pots. We find that the easiest narcissus, after Paper Whites, to force is *N. Jonquilla Campenellii*, and it is so much more dainty than many of the others that it is a great favorite with ladies.

If *Iris tingitana* is grown, be sure that it is kept in a cool house as it will never flower if forced in heat.

Giganteum lilies when potted are better placed under a bench where there is no danger of drip and drawn up about four inches. If this is not done they come very short in the stem. Giganteums like a temperature close to sixty degrees at night from the time they are started until the first flower begins to open, when they may be hardened off by removing to a cooler house. *Lilium formosum*, we find, does better grown cool and we think on the whole is a better lily for the private gardener. *Lilium candidum* also does better grown cool and is a very graceful lily when in flower. *Lilium regale* has not so far forced well with us, but my friend Wm. Anderson of Lancaster, Mass., says that if kept over in the same pot it does much better the second year.

Tropical plants will now have about completed their season's growth and from now on and for some time stimulation will not be necessary. If such plants as *Croton* are forced into growth at this season, a soft set of leaves is likely to be the result, if we have a long period of cloudy weather they might drop. The shade may be removed over the crotons and a night temperature around sixty degrees maintained, giving plenty of air on all favorable days. By this treatment the leaves will color nicely and the plants will get good and firm which will cause them to give much better satisfaction when used for decorative purposes.

Marantas will require a similar treatment as the above, only must be shaded a little longer on bright days than crotons. The same is true about alocasias, anthuriums and other tropical plants of similar nature.

Any gloxinias, tuberous-rooted begonias, achimenes, fancy leafed caladiums that are going to rest, dry off gradually and when the foliage is gone they may be placed in a dry position where the temperature does not fall much below sixty degrees. We have seen many of them lost by trying to rest them in a cool temperature. Plants in flower just now are gloxinias, allamandas, flowering anthuriums, *Pancratium fragrans*, dipladenias, *Clerodendron Balfourii*, *Eucharis amazonica*.

This is the best time of the year to secure soil for potting. Get a good tough sod from an upland pasture and stack it up with layers of cow manure in between, also adding a good sprinkle of bone meal. We think it is better not to add lime to the compost heap as when one comes to use the soil, many greenhouse plants of a hardwood nature do not like it. Lime may be added when mixing for potting when the plants require it.

As the cool nights arrive, the roses will need stimulating. We give a slight topdressing once a week using alternately bone meal, goat manure, Clay's fertilizer, tankage and dried blood. Cow manure we think is better used in a liquid form. If put on the rose bed as it comes from the barn it is apt to make a soft growth, the leaves then becoming more subject to black spot and mildew.

Finish potting any of the late fruiting pot fruit trees. Grapes will now be ripening fast and plenty of air is in order. Keep the atmosphere as dry as possible. The principal thing now will be to get them in a condition to keep as long as possible and I think hanging on the vine is the best place for them. If cut and put in the fruit room in bottles with water in them, we think they lose a good deal of their flavor.

Look carefully after the strawberry plants intended for forcing next Winter. Now is the time when a good crown is built up by careful watering and feeding.

Orchids from now on will need more careful watering. Allow the compost to get quite dry before watering on *Dendrobium Phalaenopsis* and *Cattleya labiata*. *Dendrobium nobile* will be finishing up their season's growth and may be removed to a cool house and gradually dried off; also the Wardianums as soon as growth is completed. *Phalaenopsis* must also be more carefully watered, and look out for slugs or they will soon destroy the leaves and any flower spike that may be pushing up.

Give the calanthes plenty of room and feed them well as they are finishing up their bulbs, and begin to develop the flower spike.

Look out for sudden changes in the temperature. On raw cool nights fires will be in order.

THINGS AND THOUGHTS OF THE GARDEN

(Continued from page 252)

markets while gladioli, dahlias and asters have gone a begging, perhaps because buyers realize that they are everlasting. Statice particularly are coming into their own each year. These charming flowers have an immense sale abroad and the number of bunches sold in Covent Garden Market is almost unbelievable. While a fair number of the hairy *Statice latifolia* are included, the majority are of the annual varieties like *Bonduelli*, yellow, and the mauve, white and primrose colored forms of *sinuata*. *S. Suworowii* succeeds much better in pots than outdoors and can be flowered from Christmas until the end of June, by starting seeds at intervals. It makes a very nice pot plant and is of remarkably easy culture in a cool house. There is a white as well as a colored form of this statice, which is a native of Western Turkestan. *S. profusum*, a greenhouse hybrid is a sub-shrub, sometimes seen 3 to 4 feet high and 5 to 6 feet across when grown into specimen size abroad, this is blue-purple in

color, with a yellowish corolla. The grand specimens of this variety will be very well remembered by many members of the craft.

*

I read with much interest in one of our English contemporary magazines of the fortnightly meeting and exhibition of the Royal Horticultural Society in London on August 9, these meetings always bring out numerous exhibits and are largely attended by the garden loving public. I was more especially interested in the bestowal of an award of merit to what is described as "an elegant-lady fern, has pale green arching fronds which are crested at the apex, and also at the end of each of the pinnae." The plant thus described was shown by Amos Perry, a noted hardy plantsman under the name of *Athyrium filix-femina angustatum mediodecapiens corymbiferum*. The British ferns are a most interesting class, but years ago when helping to handle a large collection, I was always glad that Latin had been included in my school curriculum, yet nowadays students in college horticultural courses are not asked to take Latin at all, or have a choice of French or German. A knowledge of the several ancient and modern languages may not be necessary to make a man a successful gardener, and one who can produce good plants, but I have always insisted that it would be a great asset for a young man planning to follow floriculture or the broader field of horticulture as a profession to acquire a knowledge of Latin, as it would be of inestimable value to him in pronouncing and knowing the meaning of plant names. Next to a command of English I would place Latin as the most valuable language for a gardener to have a fair knowledge of.

HOW OUR WILD FLOWERS CAN BE PRESERVED

THE ultimate fate of the varieties of wild-flowers which are threatened with extermination lies with the motorists. Other causes combine to hasten this process near the centers of population, including the picking by school children and holiday makers; but the motorist alone goes far afield to the natural reservoirs where enough seeds might still be grown and disseminated to counteract the diminution of the supply near the cities. In the remoter country districts the flowers are in small danger of being intensively picked by the rural population. But the motors bring countless pickers, of every grade of science, eager to seize every rarity they see. The complete disappearance of conspicuous varieties from the more traveled highways is proof sufficient of the crying need of a better understanding of conditions by the motorists. There are flowers to be picked and others not to be picked, and only study can differentiate between them.

Another reason for the disappearance of some of the favorite American plants from the haunts where they used to be most plentiful is the use of great quantities of evergreen species for winter decoration, especially at Christmas time. The picking of the Christmas fern and of ground pine is on a very large scale in many places, but most harmful of all is the unrestricted winter picking of laurel. Laurel makes its leaf growth after flowering in June, so that picking the flower branches is only temporarily harmful, if it is not done on too wholesale a scale. When one realizes the twenty years' growth of a laurel plant is used in every yard of laurel rope one appreciates the destruction caused by the Christmas church decorations. There are plenty of excellent substitutes. Beautiful decorative effects are possible with pine branches.

Work for the Month in the Garden

SAMUEL GOLDING

THE recent climatic conditions have been most favorable to the growth of late crops, and the outlook at the time of writing is most encouraging and full of promise for good supplies of late vegetables.

The advent of Jack Frost cannot now be long delayed and we realize that the time of seeding is over for the season in the open ground, and our efforts must turn to harvesting the ripe crops and to some means of protection for the more tender subjects, endeavoring to prolong the supply, and conserving whatever possible for use during the long Winter ahead of us.

Lift the main crop of potatoes as soon as they are ripe, especially if the weather conditions are favorable, as they will gain nothing by being left in the ground. Spread the tubers out in a cool, airy place to dry. If disease is present, they can then be carefully gone over and the diseased tubers removed when storing away for the Winter.

Carrots and beets may be lifted and stored away in the root cellar, but failing this, they may be placed in sand in a frost proof shed.

See that the onion crop is properly dried and harvested. Before storing, it is advisable to turn them over occasionally. Keep those with thick necks for immediate use, as their keeping qualities are poor.

During this month celery will make rapid growth, and it is important that we keep ahead by earthing it up. During the early weeks of October the rust is generally more prevalent, and where it appears it will demand much attention to combat it. Remove and burn the diseased leaves, and spray with Bordeaux mixture to prevent its spreading.

Tie up the leaves of cauliflowers over the hearts to keep that desirable white and clean appearance. Tie up endive to blanch and have space ready in frames where some may be placed in case of early frosts.

Remove the lower leaves from the Brussels sprouts to give them the benefit of all the light and air possible. Keep the hoe going between the rows of late spinach, kale, etc.

Have a supply of salt hay or other suitable protecting material to protect beans and lettuce, if necessary. Make a point of having the sashes ready in case of sudden frost, to cover late crops growing in pits and frames. Give these plants every encouragement to make good growth. As soon as the land is cleared of early crops sow Hairy Vetch and rye as advised in last month's calendar for plowing in for green manure in the early Spring.

Remove the runners from the young strawberry plants and cultivate to encourage the formation of fine crowns for next year's fruiting.

Commence to collect material for mushroom beds for Winter supply.

Push on with the planting of new peony beds; divide and transplant where necessary in September, giving them a cool and rooting medium.

Divide and transplant the Oriental Poppy in September, and make root cuttings of any particular varieties you wish to increase.

This season has been particularly favorable to the growth and abundance of bloom among the perennials

and Summer-flowering bulbs, such as *Physostegia virginica*, *Veronica longifolia*, *subsessilis*, *Cimicifuga simplex*, *Artemisia lactiflora*, *Eryngium amethystinum*, *Salvia farinacea*. The last named, although fairly hardy, is best treated as an annual. It makes a fine combination with the above, which are all worth a place in the garden.

The newer varieties of montbretias are among the brightest and most attractive of Summer flowering bulbs. Their merits need to be better known to be properly appreciated. The colors range through yellow to scarlet and are fine for garden decoration and lasting as a cut flower. The bulbs need protection during Winter where they are established, or they can be taken up and given treatment similar to gladiolus bulbs.

Continue to give dahlias every attention until cut down by the frost. These flowers are enjoying well-deserved popularity now. Many and increasing numbers of amateurs are falling under their spell, as a visit to the forthcoming dahlia shows will fully demonstrate. Each year we find improvements on the varied types, whether for use as bedding plants, garden decoration or cut flowers.

During September the perennial borders are gay with flowers of many hues and colors. The perennials, annuals, gladioli, cannas and dahlias vie to create a picture unsurpassed at any other season of the year. But the frost may be here at any time to take the most tender, although some may persist throughout October, or until the first real killing frost.

Some protection is necessary for the later blooming hardy chrysanthemums. They are well worth the little extra trouble it may take to keep early frost from injuring them.

If any alterations in the gardens are contemplated it should be done at the first opportunity. If these are carried out early in October the ground is warm and the newly planted stuff will commence to form root which will help them to winter well. It is best to transplant Spring and early Summer blooming subjects early in the Fall, and Fall and late bloomers in the Spring.

See that newly sown lawns do not suffer from drought. The late sown seed will need every encouragement to become well-established before severe frosts. Push on with moving and transplanting evergreens and avoid all unnecessary exposure of the roots to the sun and wind, and water well after planting if dry weather prevails.

Many varieties of fruit will now need attention. Apples and pears will be fit to gather when the fruit is easily separated from the tree, when gently lifted.

To keep grapes, they must be kept free from insects, and good bunches should be protected by cheese cloth bags.

THE MASSACHUSETTS AGRICULTURAL COLLEGE, co-operating with the National Association of Gardeners, has introduced a course for training young gardeners, where they can obtain both a theoretical and practical knowledge. Full information may be obtained by addressing

PROF. FRANK A. WAUGH,
Massachusetts Agricultural College,
Amherst, Mass.

Statice—Thymus

RICHARD ROTHE

STATICE, the Sea Lavender, is a large genus of the order *Plumbaginæ*, many species thereof inhabiting saline districts and sea shores. The mere mentioning of the name will bring back into the memory of older horticulturists, of European training, rows of bundles of tiny blue and lavender blossoms hung up for drying to be used for funeral design work of immortelles in vogue twenty-five to thirty years ago. Fashions and material have changed and many of us have nearly forgotten the sea lavenders with their tufts of long smooth leathery foliage and their graceful panicles. However, growing some of the best hardy perennial species today we will find that those graceful panicles of tiny blue and lavender blossoms during August can be used for the same purposes as we use *Gypsophila paniculata* in June and July. According to my experience the sea lavenders merit by far more space in our hardy borders than they have hitherto been given.

Statice latifolia.

The number of Mid-Summer flowering rockgarden inmates is not over abundant. *Statice* intelligently placed can be easily made an effective July and August feature. For perfect development all species require an open sunny exposure. On account of their deep root system they rarely ever suffer during prolonged draught.

The garden forms generally known are mostly natives of eastern Europe and Asia. *Statice eximia* produces panicles of handsome pale lilac blossoms; *Statice Gmelini* is distinguished by violet blue flowers; the stateliest species of the hardy sea lavenders, *Statice latifolia* shows freely branching heads in clear blue; while *Statice tartarica*, syn. *S. incana*, as the lowest growing garden variety adorns itself with purplish pink panicles.

All sea lavenders require a well manured and deeply dug sandy loam and may be raised from seed sown in cold frames in Spring or propagated by root cuttings. Their evergreen foliage requires leaf covering as Winter protection throughout northern states.

THYMUS

Of *Thymus*, a genus of the order *Labiata* consisting of mostly hardy small shrubs or undershrubs, all this note deals with are the few hardy herbaceous low creeping species of Central Europe and the British Islands. Under cultivation they form dense vivid green mats of

aromatic vines, which, during the later parts of June and in July appear covered with clouds of little blossoms. In height, not exceeding 2-3 inches, mountain thymes prove very pretty subjects for sunny rockeries and dry walls as well as for the filling up of crevices of slab stone formal garden walks. *Thymus serpyllum album* flowers snow white; the blossoms of *coccinea* are red; while *serpyllum splendens* produces flowers of magenta color. Our illustration, a reproduction of a photo taken in

Thymus serpyllum splendens.

Northeast Harbor, Maine, shows the marvelously rich floral effect which in the North is of a brilliancy never reached throughout the Middle Atlantic States.

The less known species *Thymus lanuginosus* resembles in habit of growth the *serpyllum* type. Its distinct characteristics consist of a woolly hirsute foliage of a mouse-gray shade and little flowers of purplish lavender hue.

Aside from open sunny exposure, mountain thyme thrive best in a light sandy loam. Stock can be raised from seed sown early in Spring. Propagation by division early in Fall. Plantations in northern border States should be protected by light leaf covering unless thick and permanent snow covering can be depended on.

AUTUMN GLORY AT ENGLISHTON PARK

(Continued from page 255)

maples, the yellow cucumber magnolia, the coloring oaks,—and I find the scarlet oak a finer tree than the red oak,—the golden tulip trees and red dogwoods. Such a planting as this with evergreens of every hue and character interwoven is as beautiful and restful a vision as one wishes, upon which to cast tired eyes.

These notes may give a few suggestions to garden lovers and planters. Fall inspires us toward certain kinds of planting, and Spring has her own especial lesson in which to instruct us. There is perfect harmony in heart and garden if one is keen and alert to all that Nature tries to teach us. Byron said in "Childe Harold" that there is no solitude when communing with Nature, and this is especially true with Nature in her Autumn garb.

The Rock Garden

ARTHUR SMITH

(Continued from the August issue.)

THE following descriptive list of alpine and other plants suitable for a rock garden must not be considered in any way complete, a brief selection only has been made of those considered best for American conditions, all of which have been cultivated by British specialists in rock plants for many years. In the case of several genera, hybridizers have been at work for some time and varieties have been raised which in a number of instances have proved to be more at home in lowland gardens than their types.

Acaena microphylla. This is attractive by reason of its showy crimson spines which are borne on the calyx. It has several distinct varieties and is used as an evergreen ground cover over bulbs. Spreads by creeping rootlets and may be propagated by division, seed and cuttings. (Native of New Zealand.)

Acantholimon glumereum. Height six inches; leaves evergreen. This has the advantage of blooming later than most kinds. July to September. It has rose-colored flowers. Slow growing and requires all the sun possible. Propagated by seeds, which are slow in germinating; by cuttings made in late Summer and wintered in a cold frame; division is possible, but it does not take kindly to this method. (Armenia.)

Achillea. Most of this genus are too coarse for the rockery, but *tomentosa*, with its downy foliage and yellow flowers, has a distinctive effect, especially against red sandstone rocks. This is native both of this country and of Europe. *A. rupestris*, considered by some a better kind, has white flowers. (Native of Italy.)

Adonis vernalis. This has showy, large yellow flowers in early Spring. While not classed among the choicest of alpine, it is an easy doer and readily raised from seed. (Apennine Mountains.) Other species are *amurensis* and *pyrenaica*.

Æthionema pulchellum. Flowers pink, May and June; leaves glaucous. This is a beautiful plant allied to *Iberis*, and easily propagated by division in the Autumn. Should have a sunny position. (Central Asia.)

Alyssum saxatile compactum. Well known, and one of the most popular of rock plants. As its name suggests, the variety *compactum* is closer growing and therefore more suitable for rock gardening than the original. There are several other forms having different shades of yellow flowers, and one with double flowers and variegated foliage, but none are really better than the above. Easily grown from seed.

Andromeda polifolia and *glaucophylla*. These small native sub-shrubs are not so well known as their beauty deserves. They should have at least some shade, with plenty of leaf mold or peat in the soil. They have neat and compact growth, but become rather too large for a small rockery.

Androsacca. Rock Jasmine. Alpine Phlox. No genus of the mountain flora is more charming than this. It is principally found in the higher ranges of the European Alps and Pyrenees, and there are one or two species on the Himalayas. They are not of the easiest culture and it is useless to attempt growing them unless the air is absolutely pure at all times, for they will soon die in the neighborhood of towns. They like a little shade, from an overhanging rock, for instance, that is sufficient to shelter them from the midday sun. They should always have

small stones placed around their collars. Propagation is by seed sown in pans, and by division in Autumn.

The most popular species is *carnea*, having flesh-colored flowers with yellow eye and is a most beautiful species. It has trailing shoots. (Himalayas.) *Sarmentosa* is a charming plant also from the Himalayas. It is of rather small growth and should be covered with glass during the Winter. Limestone chips are the best to use around its collar; *villosa* is a great favorite with alpine growers in Britain. It has gray leaves thickly covered with fine hairs and its pink flowers are borne in umbels. This species should have some broken limestone mixed with its soil. Among other species are *chamaejasme* with crimson flowers, also liking limestone; *glacialis*, very dwarf, with pink flowers, rather difficult to grow; *filiosa* is a vigorous grower with rose-colored flowers, likes lime; *vitaliana* is distinctive by reason of its yellow flowers, and is a delightful object when nestling in a rock crevice; dislikes lime.

Anemone. Most botanists today place the lovely native *Hepatica triloba* in this genus. It is splendid for the rockery provided a shaded spot can be found for it, and is one of the most valuable and earliest of Spring flowers, and the coppery tint which its foliage puts on in Winter produces a beautiful effect at that season. It is common in our eastern woods among rocks, from whence it can be easily collected, as it transplants readily, but care should be taken that its roots are not doubled up in replanting. It is native from Labrador to Florida. *A. fulgens* has scarlet flowers in May and June and makes a brilliant spot of color, and it is a vigorous grower; *occidentalis*, also known as *alpina*, is a western native species with bluish-white flowers in May; it thrives best when limestone is mixed with the soil. All Anemones can be increased both by seed and divisions.

Aquilegia. Most of this beautiful genus are too tall for rockeries, but there are several alpine and sub-alpine species, native of North America as well as of Europe and of Asia, which can be used. *Alpina* is native of the Swiss Alps and has blue flowers; *glandulosa* is another dwarf species from Siberia and is one of the handsomest; it has blue and white flowers; a variety of this, known as *stuarti*, is equally charming and longer lived than its parent; *jonesii* is the dwarfiest and most tufted of Columbines; it has blue flowers in July and is native of Wyoming and Montana. None of this genus are really long lived plants as perennials go, but as they are easily raised from seed there is no difficulty in keeping up a stock of them.

Arctostaphylos. This is allied to the Trailing Arbutus, and like it, evergreen. There are several species native of America, but only a few, which are mostly trailing, are hardy in the northern states, these being quite good for rockeries. The flowers are small, white tinged with red, but the chief value of these plants is for the effect of the red fruit, which persists during Autumn and early Winter. The hardiest species are: *Uva-ursi*, Bearberry, native all over the northern States and south to Mexico; *nevadensis*, found on the higher mountains of California, has larger flowers and foliage and should only be used where there is plenty of room; *tomentosa* is a more upright species native of the northwest; *alpina*, the smallest, grows as far north as the Arctic regions. Partial shade is beneficial to them, and when not covered with snow, light protection from Winter sun is advisable. Propagation is by cuttings of mature wood taken late in Summer and rooted under glass.

Arnebia echioides. Prophet Flower. This is remarkable for the five dots which it has upon its yellow flowers, black

at first, but which gradually fade away. These dots, which are legendary as marks of the fingers of Mahomet, have given the plant its common name. It is exceedingly pretty and does best with partial shade. Easily propagated by stem or root cuttings and also from seed. (Native of the Caucasus.)

Aster. Of this well known genus *alpinus* is the only species suitable for rockeries, and for this purpose is very popular in Britain. There are varieties with pink, blue and white flowers. (Occurs in the Rocky Mountains.)

Aubrietia. Rock Cress. This is generally considered as one of the indispensable rock plants, it being unequalled in beauty, hardiness and ease of culture. It is, however, of rather a rambling nature. *Deltoidia* is the most important species, with purple flowers in Spring. *Fire King* is a variety with crimson flowers; there are *campbelli* with violet and *leitchlini* with rose-colored flowers. The general practice is to clip them back after flowering. They withstand drought well and should have a sunny position. Increased by division and by seed.

Campanula. Under the name of Canterbury Bells this genus has for many generations been one of the indispensable plants of old-fashioned gardens. There are also a number of alpine species, of which some at least should never be excluded from rock gardens. One of the best known of the latter is *carpatica*, which has both blue and white flowers. This is native of the Austrian Mountains, and has several named varieties, of which *riverstia* is the best, having rich blue flowers, and is one of the most pleasing of the Harebells; *rotundiflora* is the common Harebell, and is found in Europe, Asia and America. The species having the darkest blue flowers is *pulla*, from the Austrian Mountains. A rather rare western American species is *scouteri*, but it has a more straggling growth than the others mentioned.

Coptis trifoliata. Gold Thread. This is a small evergreen found on the Adirondacks. It receives its common name from the slender, thread-like, golden-yellow roots. Flowers, which are both white and yellow, appear in June. Should have a partially shaded place and requires plenty of moisture. While not one of the choicest of rock plants, it is worthy of a place that can be filled with nothing better. Propagated by division and by seed.

Cornus. Even among those possessing considerable horticultural knowledge are to be found many who are unaware of the two beautiful dwarf species, native of this country as well as of others, which this genus contains. Their beauty will to some extent be realized from the fact that they are practically miniatures of *C. florida*, as, like it, it is their bracts, not flowers proper, that are the principal source of their attractiveness. *C. canadensis*, **Bunchberry**, is one of those chaste gems of the floral world which delight all plant lovers. It grows about six inches tall and spreads by underground stems. It is generally at its best in July, after then its beauty is prolonged by the red fruit and foliage; *succica* is very similar and quite as handsome, although its "flowers" are slightly smaller, but they have the advantage of appearing a month later. They should have partial shade, and it is impossible to supply them with too much water during the Summer.

Daphne. Of this genus *cneorum* is well known in borders, but it does better under rock garden conditions. Its fragrant and beautiful pink flowers in Spring and later on delight all who know it; *blagayana* has white flowers which are also fragrant and is one of the best of the genus for the rockery. It is rather more trailing in its habit than the other, and can be readily propagated by layering. *Daphnes* prefer a soil containing lime and should have a top dressing of rich, gritty compost shaken among their stems every year.

Dianthus. This genus contains a wide range of well-

known plants from the Sweet William to the Carnation. A few of the dwarf hardy pinks have much to commend them for rockery purposes. They like plenty of sun and should have their collars surrounded by small stones, limestone chips being preferable. The following are the best suited for rock gardening, although there are others which may be used: *Alpinus*, *glacialis* and *cinnabarinus*, all native of Europe and Asia. Propagated by seed and by cuttings.

Dodecaniheon. Shooting Star. American Cowslip. This genus is spread all over North America and is also found in Asia. It contains some charming and graceful rock plants, which require a cool, moist, partially shaded bay to do their best. The flowers of individual species vary much in color. The most common is *media*, which is found from Maine to Texas; a variety of this, *integrifolium*, also known as *jeffreyanum*, with rosy-red flowers, is native of the Rockies. The most beautiful species is *cleve-landi*, which grows in California, but it is not hardy in the northern States. Propagation is by division of the crowns and by seed.

Erica. Heath. The Heaths are mostly compact in growth and carry a profusion of flowers and are well suited for rock gardens. Those best known in this country and which are hardy in the northern States are: *vagans*, Cornish Heath, and *vulgaris*, (*Calluna vulgaris*). The writer has known *vagans* to go through the Winter all right without protection except that it was in the shade, where the temperature fell to twenty-two degrees below zero; and *vulgaris*, which is the Scotch Heather, has withstood thirty-five degrees below zero in an exposed place, but covered with pine boughs. There are both pink and white flowered kinds of these. *Carnea*, Alpine Forest Heath, is little known in this country, but it is a jewel among the hardy Heaths and is the most popular of the genus among the rock gardeners of Britain, it being as hardy as a lichen. It has rosy-purple flowers early in the year; like the others, it has white varieties. This likes some limestone in the soil, and may be propagated by division; but they are all easily raised from cuttings of the growth of the year taken in August or September, rooted in sand in a close cutting box, and when rooted transferred into small pots and wintered in a cold frame. The compost for the pots should be three parts leaf mold and one part sharp sand. As they grow slowly, it is best to carry them for a year in pots, placing shade over them in Summer. There are other *Ericas* more or less hardy in this country, but the above three are the best and most reliable.

Dryas. Mountain Avens. Evergreen trailers allied to *Geum*, of which the following are native: *octopetala*, which is the most beautiful, bearing numerous white flowers in July, but it is too rampant for a small rockery; *drummondii* and *integrifolia* are more compact in growth. Their evergreen foliage is sometimes browned by Winter sun; this can be prevented by a few pine branches. All are native of the New England mountains. They may be propagated by division in the Autumn, also by cuttings and seed.

Erinus alpinus. This is one of the most charming of the European alpinus, having purple flowers by April until June; in some varieties the flowers are white and crimson. It is best raised from seed sown where the plants are to stand.

Gaultheria procumbens. This a common eastern American creeping plant which does well in the more shaded part of a rockery, as do also *ovalifolia* and *myrsinites*, natives of the Mount Ranier district of the west; the last mentioned is very small, only two inches tall. While their white flowers are very pretty, they are principally desirable for their red berries, which remain throughout

(Continued on page 262)

September Flowers

BERTHA BERBERT-HAMMOND

AFTER the long, flowerless days of Winter, even so pallid and inconspicuous a bloom as the Snowdrop, "The first pale blossoms of the unripened year," is enthusiastically welcomed and its praises are sung in poetry and prose. But after a Summer of varied and unrestrained bloom, to gain attention and admiration the late blooming flower must be most generously endowed with Flora's choicest gifts. In this instance, as in others, Nature has done the work well and has glorified the Autumnal roadside, field, and garden, with the gayest and fairest of flowers, robed in brilliant reds, royal purples, and golden yellows. Mary Howitt expresses the thought thus:

"There are flowers enough in the Summer time
More flowers than I can remember—
But none with the purple, gold and red
That dye the flowers of September.
The gorgeous flowers of September!
And the sun looks through
A clearer blue
And the moon at night
Sheds a clearer light
On the beautiful flowers of September."

Wild flowers and those of the garden, annuals and perennials, vie with each other in contributing rich hues to enhance the brilliancy of the floral festival. The French marigolds, and also the taller African sorts with their profusion of gorgeous flowers that display golden yellows, warm browns, and velvety maroons; the improved zinnias, far removed from the indistinct coloring of the old-fashioned varieties; and the tall growing Golden Glow with its myriad of bright hued, double flowers nodding on long, graceful stems, effectively carry out a very decorative garden scheme in green and gold. Field and meadow owe their dazzling golden splendor to the yellow daisy, *Rudbeckia hirta*; wild sunflower, *Helianthus*; Jerusalem artichoke; Yellow Star, *Helium autumnale*, and numerous other yellow flowers, besides the very numerous species of the well known and highly conspicuous Golden Rod. Almost hand in hand with the bright Golden Rod comes the starry asters in many varieties and varied colors, giving those charming indescribable touches of lavender and purple to hillside and vale, that adds such wealth of color to the radiance of the countryside in September. In the garden, too, improved sorts of China asters with their profusion of bloom make a wonderful display that for beauty and splendor cannot easily be surpassed.

The graceful *Cosmos* with its feathery foliage and beautiful, long-stemmed flowers is generally classed among the late blooming annuals, but an early flowering strain has been developed, one sort coming into blossom in September and another, an extra early kind, it is claimed, from seeds sown in the open ground in May will produce bloom in August and sometimes even before then.

Though most varieties of chrysanthemums bloom late in the year, there are over a dozen covering a wide color range that are known as September flowering chrysanthemums.

The hardy Japan anemones both in the single and double flowered kinds lend to the garden a pleasing light color that extends well into Autumn. The semi-double variety, "Queen Charlotte," that bears flowers of a silvery pink color is worthy of special attention.

As mere "weeds" the pickerel weed, *Pontederia cordata*, and the blue weed, or blue thistle, *Echium vulgare*, do not find a warm reception but they possess the blue color

which is welcome in flowers. The blue of the closed or bottled gentian, *Gentiana Andrewsii*, though of a deep shade at the top of the flower is of a lighter color at the base. This blending seems to render more intense the blue at the tip of the curiously closed, bud-like flowers. It remains, however, for the lovely fringed gentian, *Gentiana crinita*, to supply in its modest way the hue that artists claim nearly matches the blue of the sky and of which the poet, William Cullen Bryant wrote:

"Blue—blue as if the sky let fall
A flower from its cerulean wall."

The continuous blooming, perennial phlox with its improved color scale plays an important part and the dahlia, gladiolus, and other flowers join in to make the September garden colorful. The gayest of them all is the scarlet sage, *Salvia splendens*, whose numerous spikes of vivid red rise like flaming plumes above the foliage. Only the gorgeous Cardinal Flower that lights up moist meadows and the banks of streams equals this intensity and brilliancy of red coloring that crown the September pageant.

THE ROCK GARDEN

(Continued from page 261)

the Winter. They are rather slow in becoming established, and the soil should be free from lime.

Globularia. Globe Daisy. The alpine kinds of this genus form evergreen carpets and their pretty blue flowers appear in July and August. They prefer a soil containing limestone, but will thrive in ordinary rock garden compost. *Trichosanthes*, native of Syria, is perhaps the best known, while *cordifolia*, *nudicaule* and *nana*, natives of Europe, are also hardy. They come easily from seed, and divisions may be made in the Fall.

Harberia rhodopensis. This is a perfect floral gem, having flowers like miniature Gloxinias. It is native of the Balkans, growing in dense tufts with flower stems only an inch or two tall. It should be placed between rocks, so that the latter will afford it some shade. It can be raised from seed and propagated by division in the Spring.

Iris. Those whose only experience of this genus is of the stately species native of our own swamps and of other countries will not be likely to think of them as rock plants. There are, however, several choice species which, by reason of their diminutive beauty and rarity can only have a chance to grow without being smothered by coarser things, and have the attention they require and deserve, in a rock garden. Upwards of a score of species are desirable for this situation, of which the following are the best suited to American conditions: *Bakeriana* is a little bulbous species about six inches tall, with blue and white scented flowers in early Spring; *crinata*, an American alpine from the mountains of Kentucky and Carolina, is one of the choicest gems of this genus, and bears its beautiful flowers in May, their standards being lilac and the falls blue, crested with yellow; *gatesii* is another beauty, native of Armenia, with silvery flowers in June; *histrion* is a bulbous kind and one of the earliest; the writer has had its pretty blue and yellow flowers push through the snow in February; *pumila*, native of the Crimea, has violet flowers with a white beard; this species has many varieties, with flowers of different shades. Irises can be readily grown from seed, and can also be propagated by offsets and by division, according to the character of their roots.

(Concluded in October Issue)

Departments of Foreign Exchange and Book Reviews

TRITOMAS.

WHEN the warm September days give place to cooler nights; when the Summer flowers begin to fade and fail, there are to be found amongst our hardy garden plants some that bring rich and intense colorings as their blooms unfold. Conspicuous in this category are Tritomas, which, amid faint suffusions on creeper and on tree, appear sentinel-like, giving to the borders a new splendor, and an added glory in the waning of the year. They are known to some as Kniphofias, or Torch Lilies. To a far greater number, perhaps, they are more readily recognized under the familiar name of Red Hot Poker. When the spikes reveal themselves in tones of vermilion, and in scarlet and yellow, we think that Torch Lily is appropriate, as they are veritable flames of color in these shortening days. Their very presence is an indication that Autumn stands like a waiting guest at the door; nay, has come, indeed, and is even now upon the threshold. It is in signs like these that Nature writes her story. And yet, 'tis true, she is a kindly visitor. As yet, her presence is but little felt, for some of our trees are garbed in all the loveliness of their Summer green. There is still a soft consenting atmosphere making the garden a pleasant place in which to linger in days that are fair. Presently, she will touch with her icy fingers the trees and hedgerows, giving to the leaves another beauty with her magic wand. By-and-by she will paint the countryside in more enchanting colors still, that each nip of frost will but intensify, until there comes a night, colder than the rest, when leaves will flutter to the ground, and then there will be seen—

"The wonder of the falling tongues of flame."

But that is yet to be, as Autumn may be genial, kind and good for a time; still it has to be said we stand at the season's gateway, and pause amid the flowers that keep us company. For resplendent dress, there is none to surpass the richness of Tritomas. What a time we have grown them, as we look back across the years, and how seldom, if ever, they have disappointed us! Their culture, too, how simple; how few their requirements, and how rarely they have entailed removal! Michaelmas Daisies, albeit prodigal with their blossoms, cannot compete in brilliancy with the flaming spikes of Tritomas that lighten the somberest corner, and then, like a tired child, go to rest.

It is, we think, because they are easy to grow, and so accommodating, that many folk look to them year by year, and regard them as true "partners in the glory of the garden" in these later days.

Conditions of Success.—And to have Tritomas in all their beauty, one is not bound down by exacting conditions; in fact, their culture is so simple that all may grow them, if they are prepared to give them a good start and a sunny position, with a thought to drainage. More than this they do not ask of us, as they will go for years without the necessity for taking up and dividing. They are amongst the few plants about which one is correct in saying that "they improve with keep," as the chief thing one need trouble about is to afford them some protection in Winter by covering the crowns with leaves or ashes or straw manure, giving them in the Spring a dressing of rotted dung. Spring is the best time also to plant them. A good sandy loam suits them to perfection.

Varieties.—There are many sorts amongst Tritomas that are so vivid in coloring that to appreciate them fully needs an intervening space, and if planted not far away from a shrub or wall over which climbing plants run, the spikes show to the best advantage. Such is *T. waria*, one of the oldest and best, met with frequently in country gardens in flaming color. *T. nobilis*, with orange red spikes, is tall and imposing, often 6 to 8 feet in height. *Nelsoni* is comparatively dwarf, with reddish crimson spikes. *Egypt*, tall, of a rich amber color. *Leda*, blooms early, of a compact habit, spikes of coral red with orange shading, a very attractive sort; *breviflora* is a late flowering sort, of slender growth, with pure yellow spikes. *Lachesis*, of a rich apricot color, distinct and handsome.

This is only a short list of some of the members of this very charming family of hardy plants, and though most of them are just now in the prime of their beauty, very often one may have glimpses of them far on into October in a mild autumn, when many other plants have ceased to bloom. If you possess Tritomas, you may go into the garden some dull October day and find a few belated spikes amid others showing points of vermilion and yellow, standing almost alone, and if you do not express it in so many words, you think they share the honors with the few

late lingering Roses on the wall, or the leaves of the Virginia Creeper, here brown and amber, there deepening into crimson carmine ere they fall—a richness that is carried to the last.—*Irish Gardeners.*

BEAUTY IN FRUIT TREES.

ONE finds wide differences in the management of plants. The object in view is the same, but the treatment to that end accepted by one grower is often diametrically opposed by another cultivator. It does not appear to me of the slightest moment what the means may be, provided that the end is achieved. A striking example of opposite methods is found in fruit pruning. Here one finds a man who cuts every shoot hard back and there one who refuses to use knife, saw or secateurs. Which of these is taking the wiser course? Personally, I should favor the latter system; covering my opinion by saying that both are wrong, since the correct course is to find the perfect medium between the two extremes.

In regard to root-pruning, the sharp division comes between the man who will, and the man who will not, do it. We see the man who will produce a tree which is handsome in its productiveness and the man who will not produce a tree which is handsome only in its straight, osier-like growths. The former goes directly to the *raison d'être* of the presence of a fruit tree in a garden. The latter goes merely to cumber the ground.

It is not, as is too commonly thought by the tyro, difficult to decide when a fruit tree demands root pruning; on the contrary, it is very simple. When the young growths are both numerous and strong—too exuberant to develop perfect blossoms—the tree requires root pruning, with intimately associated, intelligent branch pruning. Unfortunately, the grower frequently neglects the former and directs his efforts towards the removal of every shoot. Obviously the second state must be worse than the first. The roots are still too luxuriant and the growths are multiplied quite three-fold with no measurable loss of excessive vigor. The error lies in commencing above instead of beneath the surface. Although absence of blossoms on strong shoots is a sound reason for root pruning it is not the only one. Any tree that makes more than 2 feet of new growth in a season ought to be considered as a subject for this operation, and it should be dealt with as judgment directs.

The process of root pruning may be divided under three heads as follows: Trees which have been planted one season and which have made rampant growth; older trees, up to about ten years, which grow too luxuriantly to have sufficient energy to produce fruit; and still older trees suffering from the same serious disability.

To deal with the first group is the essence of simplicity. The roots are dug from their beds and immediately replanted, with the soil packed hard to their roots. If a strong root is seen it is reduced in length, but small importance is attached to these details, the repressive action coming from the mere act of lifting and extremely firm replanting.

Trees to the age of about ten years must be handled differently, since they will be much stronger in root and branch development, and individual judgment must be brought to bear on the task. A trench must be cut wholly to encircle the tree and at a distance of 3 feet or more from the bole, according to size and age. Its width may be about 15 inches and its depth 2 feet to 3 feet. If a sharp spade is used the strong roots, which cause the excessive luxuriance, will be easily severed, leaving, however, rough cuts. These do not, of course, callus over as quickly as clean wounds, and they, therefore, should be pared off smoothly, preferably from underneath, upwards and outwards. In the generality of instances packing back the earth very firmly in the trench completes the operation; in no circumstances must natural or concentrated food be mixed with the soil replaced. In the possible event of a tap-root further trouble is involved. A cross trench must be cut directly to the bole and the down-striking root sawn clean through or the whole of the previous labor will be wasted.

The third group, comprising older trees, must be root pruned in two seasons—half-way round in the first year and the remainder in the ensuing Autumn. The details of working are on all fours with those advocated in the preceding paragraph.

The best time for root pruning is from the end of September to the end of October, but it can be carried out successfully at any convenient time in the Winter when the weather and the soil conditions are favorable.—*The Garden.*

Address of Robert Cameron, President of National Association of Gardeners

Delivered at the Annual Convention in Boston

LET me welcome you to our city. Some of you have been here before but at that time our Association was merely a handful of men compared with what it is today. The Association has grown with leaps and bounds. We have members in almost every state of the Union, and some of you have come a very long distance. I assure you that you have come to a city that welcomes you and here in the vicinity of this city you will see some of the oldest gardens in this country. In this building (Horticultural Hall) you will see paintings of men who were remarkable horticulturists. Let me ask you to look earnestly at these paintings of men who in their day were masters of their specialties. In this building you will find the largest horticultural library in the world. It is not only the largest, but it contains the oldest and rarest books on horticulture. The Massachusetts Horticultural Society has just published a catalog of the books in the library I have been telling you about. It is conceded by authorities in this country and also those of Europe, to be the most complete library catalog that has ever been published. Therefore, I say to you members who have come from a distance that if you did not see anything else in the way of horticulture, but what is to be seen in this building, you would be well rewarded in coming here.

We could have held our meetings at the Brunswick Hotel, our headquarters, but to some of us this old Massachusetts Horticultural Society, that has done so much for the uplifting of horticulture in this country, is held sacred and undoubtedly our meetings with such surroundings will be more successful than if held anywhere else in this city. Therefore, it is with this spirit of intense love of gardening that we welcome you to the Hub of Horticulture.

When you were invited last year in New York to come to Boston, the members from this section had little thought at that time of the destruction that a New England Winter could accomplish to some of the finest estates in Massachusetts. Some of the estates which we had intended at that time to show you had to be given up entirely, owing to the destruction of the fine trees which spoiled the beauty of these estates for the time being. An ice storm of such severity was never known of in this section before. On our visiting days you will still see some of the horrible destruction of this ice storm and I know then that many of you will be pleased that you haven't to garden under such difficulties as gardeners who live and work along these bleak shores. Fortunately, along the seashore, the effect of the ice storm was not felt so severely, consequently it was decided to show you some estates along the North Shore which I hope you will enjoy seeing.

Throughout the country during the past year business conditions have not improved greatly. Consequently our profession has suffered somewhat from that cause. One particular outstanding cause for so few new large estates being developed at this time is the outrageous prices nurserymen are charging for plants. The injury that is being done to our profession is serious and until a law is passed to protect customers from such scandalous prices, gardening and horticulture of every description is to suffer. There is no real reason for this condition as labor is plentiful and a good deal cheaper. Our aim as professional gardeners is the beautifying of the country, therefore, our association should do its utmost to get the material such as plants, at reasonable prices so that everyone who so desires can obtain them to beautify their homes. Quarantine Bill No. 37 is one of the best things that has happened in a century to enable the nurserymen to get rich quick. This has given them an excuse for the unreasonable prices with the pretext that there are not enough plants to supply the demand.

The love of horticulture is steadily increasing and never before has there been any better exhibitions of such popular plants as Peony, Irises, Phloxes, Roses, Gladioli and Dahlias. The attendance at these exhibitions has been very large. A most wonderful exhibition of native plants was staged by the President of the Massachusetts Horticultural Society, Mr. A. C. Burrage. This was a unique exhibition and drew the largest attendance of any horticultural show that has been staged in this country. It was open to the public for ten days and 83,000 people attended this comprehensive, instructive and wonderful exhibition. New York, Philadelphia, Chicago, Indianapolis and many other cities and towns have had wonderful exhibitions of outdoor and indoor plants and flowers, thus indicating that there is no lack of enthusiasm in gardening throughout this country.

There were quite a number of men in the early part of the year looking for employment. Owing to the economic conditions of the country there were not so many positions filled as was anticipated. The reason for so many asking for change was brought about by the loss of a great number of many of the large estates reducing

the number of men in their employment, thus making it in many instances almost impossible for superintendents and head gardeners to run the estates with credit to themselves. Our country at the present moment is suffering acutely from coal and railway strikes and the outlook at the present time is anything but encouraging to those having large greenhouses on their estates.

There is one thing that we all ought to feel proud of and that is that there isn't a semblance of a union in our association. This is a point that we ought to impress at all times when there is an opportunity on the public that the motives and aims of the Association are to develop greater interest in horticulture and to bring about a closer bondship amongst all engaged and interested in gardening. To so elevate the standard of the profession of gardening that those who engage in it will command respect not only from those who employ them, but from all others.

The local branches of the Association are of great benefit to the gardeners who live in the vicinity where a local branch is located. At the meetings of the branch, matters of importance may be discussed and later on may be taken up at the annual convention. There are now four local branches and undoubtedly there will be many more in the near future. These local branches are especially useful if a convention is to be held in a city where a local branch is located. I would strongly urge members to form more local branches over the entire country.

Young assistant gardeners are no more plentiful than they have been of late years. In previous times Great Britain, Germany, Switzerland, France and other European countries kept us well supplied, but since the World War there is a decided shortage. Young American boys have not taken kindly to gardening under the old way of training. It gives me great pleasure to announce at this time that the Massachusetts Agricultural College at Amherst, in co-operation with the National Association of Gardeners, has made arrangements whereby a special course of training for gardeners is to be established. The Massachusetts Agricultural College will conduct the theoretical instruction, while the National Association of Gardeners will take the responsibility of seeing that the training in the practical work is carried on properly. The course of training is planned with the expectation of fitting men for practical gardening, either as commercial florists, nurserymen or as gardeners on estates, foremen and superintendents in parks.

The gardener of the future has not only to have a practical training, but he must have a good grip of theoretical knowledge which can only be obtained properly in a course of instruction such as is to be given at Amherst College. The first students are to be admitted on September 27, 1922. I would ask members to try and interest boys who are interested in gardening to take up this course at Amherst and to give them all the encouragement possible.

The Massachusetts County Agricultural Schools are turning out useful boys and many of them are interested in gardening. I have had several of them and they have given good satisfaction. During our sessions these courses will be discussed and I have no doubt many new useful ideas will be obtained.

Throughout the country there is evidence that the public is being aroused at the wanton destruction of our native flowers and plants. Clubs and societies are urging their members to do all in their power to protect the native flora. Let our Association go on record as opposed to the ruthless and thoughtless pulling and destroying of our native flowers and plants along our roadsides by automobilists and others. Let us also protest against the destruction of our beautiful laurel and other Christmas greens for decorations.

Our Association should continue to place itself on record as opposed to Quarantine Bill No. 37. I am like the nurserymen, I have changed my viewpoint. At one time I believed this Quarantine No. 37 was the very best thing for our protection. I have two reasons for changing my opinion of this bill. The first is because some of our most lovely garden plants are debarred from entering this country and the second is because we have no protection from the profiteering nurseryman. If we had had some protection from these unreasonable prices then I might have a different opinion about this quarantine bill. If these exorbitant prices continue, gardeners will be forced to start nurseries on the estates where they work. What we want are well grown plants at less money and more gardens.

School gardening is of immense value, not only to the children but to the parents also. What the children are taught about gardening creates a love for horticulture and in this way the beautify-

National Association of Gardeners

Annual Convention, Horticultural Hall, Boston, Sept. 12, 13, 14, 15

President—Robert Cameron, Ipswich, Mass.
Vice-President—John Barnet, Sewickley, Pa.
Secretary—M. C. Ebel, 286 Fifth Ave., New York.
Treasurer—Montague Free, Brooklyn, N. Y.

TRUSTEES (For 1922)—William H. Waite, Arthur Smith, D. L. Mackintosh, New Jersey; W. N. Craig, Massachusetts; H. E. Downer, New York.

DIRECTORS (To serve until 1923)—Alexander Michie, Long Island; George F. Stewart, Massachusetts; Theodore Wirth, Minnesota; George W. Hess, District of Columbia; Daniel J. Coughlin, New York; John Barnet, Pennsylvania; Montague Free, New York. (To serve until 1924)—William Gray, Rhode Island; William Hertrick, California; George H. Pring, Missouri; Thos. Hatton, Connecticut; Robert Weeks, Ohio; W. H. Griffiths, Michigan; Thos. W. Head, New Jersey. (To serve until 1925)—George Wilson, Illinois; James Stuart, New York; William Kleinheinz, Pennsylvania; John F. Huss, Connecticut; Edwin Jenkins, Massachusetts; Carl N. Fohn, Colorado; Joseph Tansey, New York.

SUSTAINING MEMBERS

New York—Mrs. J. J. Albright, George F. Baker, Edwin S. Bayer, Henri Bendel, Albert Clayburgh, W. R. Coe, Mrs. F. A. Constable, Paul D. Cravath, Mrs. W. Bayard Cutting, Mrs. Charles Daniels, Cleveland H. Dodge, Mrs. David Dows, Frank J. Dupignac, Mrs. Coleman du Pont, Childs Frick, W. H. Gratick, Daniel Guggenheim, Mrs. W. D. Guthrie, Mrs. B. A. Haggis, Mrs. William P. Hamilton, Mrs. John Henry Hammond, T. A. Havemeyer, Mrs. L. A. Herman, Anton G. Hodenpyl, B. H. Howell, C. O. Iselin, Otto H. Kahn, Mrs. Frank B. Keech, W. Eugene Kimball, L. C. Ledyard, Jr., Adolph Lewisohn, John Magee, Mrs. Julius McVicker, Morton H. Meinhard, Mrs. Eugene Meyer, Jr., J. Pierpont Morgan, Mrs. J. Pierpont Morgan, Stanley G. Mortimer, Mrs. Harold I. Pratt, John T. Pratt, E. F. Price, Mrs. William A. Read, H. D. Roosen, Chas. A. Sherman, Mrs. Sam. Sloan, Benj. Stern, Mrs. W. Sturberg, Dan. Tatum, Mrs. R. M. Thompson, Wm. Boyce Thompson, Mrs. Edw. Thorne, Mrs. Henry M. Tilford, Carl Tucker, Samuel Untermyer, Mrs. Harold T. White, Mrs. Payne Whitney, E. L. Young. *New Jersey*—A. Albright, Jr., Charles Bradley, Joseph P. Day, James B. Duke, Mrs. Lewis L. Dunham, Mrs. Frederick Frelinghuysen, Mrs. K. S. Goodrich, Mrs. Gustav E. Kissel, C. Lewis, Mrs. Paul Moore, Hubert T. Parson, Mrs. Manuel Rionda, Leland H. Ross, P. S. Straus, Mrs. John I. Waterbury, Mrs. Ridley Watts, Sanders Wertheim. *Pennsylvania*—Samuel T. Bodine, Gen. Richard Coulter, Mrs. J. D. Lyon, R. B. Meilen, Gifford Pinchot, George F. Tyler, Edward A. Woods. *Delaware*—Irene du Pont, Pierre S. du Pont, Harry G. Haskell. *Connecticut*—E. Dinan Bird, Dr. Tracy Farnam, Mrs. Tracy Farnam, George M. Hendee, Miss A. B. Jennings, H. F. Schwarz, W. H. Truesdale, Edward L. Wemple, William Ziegler, Jr. *Rhode Island*—Gov. R. Livingston Beekman. *Massachusetts*—Miss M. R. Case, Mrs. William C. Conant, George P. Pike, Mrs. Henry C. Frick, Mrs. Louis Frothingham, Henry S. Hunnewell, E. K. Lawrie, Henry Penn, Mrs. C. G. Rice, Prof. C. S. Sargent, Mrs. J. A. Spoor, Mrs. Bayard Thayer. *New Hampshire*—F. G. Webster. *Ohio*—F. F. Drury, H. S. Firestone, Mrs. Francis F. Prentiss, John L. Severance, H. S. Sherman, H. L. Thompson. *Michigan*—J. B. Schlottmann, E. D. Speck. *Indiana*—Theodore F. Thieme, *Illinois*—A. Watson Armour, Harry B. Glow, A. B. Dick, Clayton Mark, Mrs. Julius Rosenwald, Mrs. F. W. Upham. *Minnesota*—Mrs. Chester A. Congdon, F. H. Stoltze. *Iowa*—Mrs. G. B. Douglas. *Missouri*—August A. Busch, Dr. George T. Moore. *Virginia*—Miss Grace E. Arents. *W. Virginia*—Mrs. Arthur Lee. *Georgia*—E. H. Inman. *S. Carolina*—Robert S. Mebane

LOCAL BRANCHES

Newport, R. I.: Andrew L. Dorward, chairman; Frederic Carter, secretary.
St. Louis, Mo.: George H. Pring, chairman; Hugo M. Schaff, secretary.
Nassau County, L. I.: John T. Everett, Glen Cove, chairman; John McCulloch, Oyster Bay, L. I., secretary.
Boston, Mass.: Robert Cameron, chairman; W. N. Craig, temporary secretary, Brookline.
Western Pennsylvania: Manus Curran, chairman, Sewickley; Henry Goodband, temporary secretary, Sewickley.

OFFICERS ELECTED FOR 1922.

John Barnet, Sewickley, Pa. President
 John H. Francis, Cleveland, Ohio. Vice-President
 Martin C. Ebel, Summit, N. J. Secretary
 Montague Free, Brooklyn, N. Y. Treasurer

Boston most assertively demonstrated its right to its claim of being the horticultural hub, at the convention of the National Association of Gardeners. Chairman W. N. Craig and the members of the various committees are to be congratulated at the great success of the convention, the banquet, and the two days' automobile trips among the famous estates surrounding Boston, and the many historic points that were visited, which proved of immense interest to the visiting members, as probably at no other place in the country could such highly interesting and instructive entertainment be provided to a gathering of the gardening profession. Briefly summarized, the Boston convention was a great success.

DIRECTORS' MEETING

The Board of Directors and Trustees met in the forenoon of Tuesday, September 12, at the Hotel Brunswick, the following members being present, Robert Cameron, presiding: George F. Stewart, Henry E. Downer, William Kleinheinz, Thomas W. Head, James Stuart, John Barnet, W. N. Craig, Alexander Michie, D. L. Mackintosh and M. C. Ebel.

The purposes of establishing branches, including the resolutions of the Newport, R. I., branch, were fully discussed and it was decided to submit the views of the directors to the convention. The future policy of the Service Bureau also received careful consideration which was to be discussed further at the business sessions of the convention.

The Board generally discussed what the future policy of the association should be and recommendations are to be made from time to time when the right opportunity presents itself to put them into effect.

James Stuart, Thomas W. Head, Henry E. Downer were appointed a committee to audit the books of the Secretary and the Treasurer, following which the meeting adjourned.

TUESDAY AFTERNOON SESSION

The convention was called to order at 2:30 P. M., W. N. Craig, of Massachusetts, acting as chairman, who addressed it as follows:

I am very glad to welcome you, on behalf of the local branch of the National Association of Gardeners, to our convention here.

The first convention of this association was held in Boston at the time of the National Flower Show in 1908, with an attendance of six, and we held a convention in 1915 also, when Mr. Curley was mayor. Our membership is now about eleven hundred, embracing a large number of the best professional gardeners of the United States. This organization came into existence as a sincere effort to elevate the standing of professional gardeners, not as a trades unit, but as such a unit as would appeal to employers of estates throughout the country. We want to work in co-operation with the estate owners, and have done so successfully, as is proven by the fact that we have on our list a large number of the most prominent estate owners of the United States.

We have several prominent speakers here this afternoon to address us and I don't want to take up any more of your time.

I am sorry that I cannot introduce to you as the first speaker the Honorable James M. Curley, of Boston. He is unable to be here because politics are humming now and politicians are busy. This is Primary Day. But Mr. Curley has sent here E. Mark Sullivan to take his place. Mr. Craig introduced Mr. Sullivan.

MR. SULLIVAN SPEAKS FOR THE MAYOR

Mr. Sullivan, welcoming the attendants to the convention, and expressing regrets that Mayor Curley could not be present, said:

Now the Mayor feels, out of a keen appreciation of the importance of your work, that this convention held in our midst merits the formal acknowledgment of the government of the city of Boston, and he regrets exceedingly that the immediate necessities of the great issue which is before him and the electorate for decision prevents his being present on this occasion to say such a word as would be becoming to the chief executive of the city.

However, I want to assure you that I come instead not as a mere perfunctory and one without keen sympathy for your great work. I, too, bear close kindred to your work. There comes from my native town the president of this association, Mr. Cameron, who is now located there, the town of Ipswich, and as far back as I can remember my father was either park commissioner or cemetery commissioner of our town, and in fact, the entire working force of both departments.

So that the work that you men are accomplishing in a large, scientific way, my father performed within his small village in a less skilful, but a most industrious manner.

Your work is something more than a mere livelihood to you men. You speak in various languages to the great public that rushes by in the train or rushes by in the automobile, giving a casual glance at these great works that you have laid out with so much thought, pains and care. And after all, they represent your creative work. From recent philosophy we understood there were several contributing causes to any work, and the main cause was the method cause, the conception, and yours is translated into these magnificent plots, of so many of which Boston can boast.

Take the magnificent estate Mr. Cameron is presiding over, owned by Mr. Crane. It is set there on a high cliff at the mouth of the Ipswich River, with a commanding view of the entire Gloucester Bay that reaches from the deep arm of Cape Ann even to the Isle of Shoals. As a boy, that estate and its possibilities were first regarded by John B. Brown. Today Mr. Cameron has under his charge an estate that is so highly valued, not because of the buildings that are set upon it, palatial as they are in character or structure, but because of the fine art which it has disclosed to men who can appreciate it and all the possibilities of that magnificent thing.

The city of Boston is indeed the city that eminently merits the great honor you confer upon it by meeting here again. Boston and its people have been quick to appreciate the work of beautifying its parks. We have been generous, even to the point of being charged with extravagance, in our appropriations for that purpose.

Flowers—they express so much! It is a tribute to Nature and to Nature's God. It is a cultural expression, capable of appreciation by all men, because the basis of real culture is not necessarily letters and learning. There may be a refinement, a cultural refinement even in men and women who know very little of what is contained in the books.

Boston has felt your influence. Boston has sought your aid and skill. It is the hope of our Mayor that we may continue to promote what may be spoken of as these vast enterprises of horticultural endeavors, because to beautify our city means to have a refining influence upon those who come to dwell in our midst. Therefore, my coming here today on behalf of the Mayor is to represent his sincere purpose, as you have seen him accomplish it, in these great endeavors, the public playgrounds and those vast expanses for recreation that are to be found here. So it is that I, too, accept the delegated invitation sincerely to come here and speak in his behalf before you good men and women.

I hope the fruits of this convention will be far reaching, will be permanent, and that as a result of it all you will leave this city strengthened in numbers, strengthened in influence and with an increased initiative for continued progress.

Mr. Craig announced that William Gray, superintendent of the estate of Princess Christopher of Greece at Newport, was to reply to the address of welcome from the Mayor or the Mayor's delegate. As he was unable to be here, he asked D. L. Mackintosh, of New Jersey, to do that duty.

MR. MACKINTOSH RESPONDS

Mr. Mackintosh responded as follows: It would be a hard thing for me to reply in an intelligent manner to all that Mr. Sullivan said at a few moments' notice.

You know you are a much older city or a much older part of the country than what we are in New York and New Jersey. Last year when we had the convention in New York our now honorable president took the liberty and had the audacity to twit us that we were all wrong in colors. Well, that wasn't very easily swallowed. He told us that we had nothing but glaring red and blazing yellow and that if we would come to Boston we would see beautiful pinks and mauve and lavender. I suppose your exhibition is put up as a lesson for those of New York to take away with us.

I don't wonder very much at that. As I stand here looking into your different faces I can readily understand that the most of you instead of being brought up on Borden's Condensed Milk were brought up on porridge and sorduck, so that you grew up to the age of manhood and discretion, if not you, your fathers, in the land of the Scotch bluebell, the most lovely shade of blue that any painter has been able to produce, and in your eyes, your mind's eye, you carry that shade of blue. And then the great majority of you had the pleasure of seeing a thousand acres of the most beautiful pink that ever could be put together in the form of heather spread over the mountains of Scotland and the wild, rugged hills of Ireland. No painter has been able to make any pink shade to surpass the heather.

When you have so many of these men with these fascinating colors in their mind's eye, do you wonder that these colors predominate—pink, blue, mauve? We in New York are of a different type altogether. I heard President Wilson say that New York was the largest Italian city in the world. It is also the largest Spanish city in the world. Now you know that an Italian always has in his mind's eye that blazing red that comes vomiting out of the top of Mount Vesuvius. He never can forget that red, and the Spaniards can never forget the yellow of their flag. So why wonder at us going ahead for yellow and red? Different nationalities have their different traits and we all cater to our own traits. What is the difference? We are pleased and you are pleased.

While being sitting down I would like to thank, on behalf of the association, Mr. Sullivan for the splendid talk he gave us, and I would like to extend our thanks to the Mayor for the excellent man he sent as a substitute.

Mr. Craig announced the next speaker as a gentleman who

needs no introduction. I am now going to introduce to you Mr. Cameron, who will now give his presidential address.

PRESIDENT ROBERT CAMERON

Robert Cameron, of Ipswich, Mass., then read his address (which appears on page 264).

Mr. Craig introduced Arthur W. Gilbert, Commissioner of Agriculture of Massachusetts.

ALBERT W. GILBERT, COMMISSIONER OF AGRICULTURE, MASS.

Mr. Gilbert replied: I feel a little personal interest in this convention, in you, and in the work that you are doing. I have never had the pleasure and the honor of being a professional gardener, but for several years I did have the interest and the experience, and I might say the enthusiasm of being a plant breeder.

Now in the few minutes that I have allotted to me I want to present to you another subject which is very close to all of us. It applies not only to those of you who are living in the Commonwealth of Massachusetts and nearby states, but possibly to others, and I believe it has a direct bearing upon the work which you are doing. You are aware, perhaps, that the agriculture of the Commonwealth of Massachusetts for the last thirty years has been going downhill. This applies also to other Eastern states. We have forty-two per cent less cultivated land in this state than we had thirty years ago. The greater center of food production has moved westward and has left us in the East in a very serious predicament.

Do you realize, my friends, that we are sending out of New England every year five hundred million dollars for food?

Now this is a very serious situation. We are located where there are very few natural raw products. We are a great industrial centre, as our chairman said.

The result of this is that the Eastern states are finding themselves in the most critical industrial situation that they have ever faced, and therefore, my friends, I am taking the liberty for just a moment to tell you that we are trying in every possible way and at every possible time to preach the raising of greater quantities of food in the East. If we are so far away from the centres of raw materials, we must bring ourselves nearer the centre of food production by raising greater quantities of food here.

Now I state this for two reasons to you. In the first place, you as professional gardeners, raisers of plants, primarily ornamental plants I assume, can be of great assistance to us, because at a time like this, we need all of the skill which you men and women possess. We need in the East the best agriculture that can be found anywhere. We haven't the advantage of the fertile prairies of the West. We have to raise our food on the rocky hillsides of the East, and if there is any place in the world where there is greater need and opportunity for skill it is here, and you are the men and women who represent, to my mind, the acme of this skill, and we want to get from you all of the experience and all of the interest which you possess in helping us to carry out this program.

I bring this to you for another reason. As your President has said, your business in general depends upon industrial prosperity. Perhaps you may feel the pinch of the lack of that prosperity as quickly as anybody else, and therefore it behooves us to help in every possible way to maintain the industrial and commercial prosperity—and I might say, supremacy of the Eastern part of the United States.

I am very glad to see, as your President has also pointed out, that the Massachusetts Agricultural College is going to offer a course in gardening. I have the pleasure of being a trustee of that college, a graduate also of that college, and I assure you that I shall do everything possible to help to stimulate this course, to bring it to a high state of efficiency, and to help you in helping to maintain and carry it out. I am glad that it is being done not by the college alone, but by the college in conjunction with this organization. This is one of the first direct tie-ups that we have between an agricultural college and an organization, and I congratulate you, my friends, that you have been one of the first to bring about a close contact with a college.

If the State Department of Agriculture can be of any assistance to you at any time you know that we will be glad to help.

In introducing the next speaker, Mr. Craig said: It hardly seems necessary to introduce the next speaker to you. You have been told about the wonderful exhibition of wild flowers we had here last May which attracted the attendance of approximately 85,000 people. You may have seen, or at least you have read of the wonderful displays of orchids we had here month by month the year before last and the great orchid displays made here by the next speaker.

Mr. Burrage was awarded the George R. White medal of honor recently for the most eminent services conferred to horticulture by any living American during the past year. He is not only President of the Massachusetts Horticultural Society, but of the American Orchid Society. We will be his guests and be privileged to view his fine collection of orchids next Thursday morning.

ALBERT C. BURRAGE

Mr. Burrage responded as follows: After such words of introduction I hardly know what to say within the three minutes allotted me by your Secretary.

The Corporation Counsel of the City of Boston on behalf of the Mayor, has extended to you the welcome of the City of Boston. Dr. Gilbert, the Commissioner of Agriculture of the Commonwealth of Massachusetts has extended to you the welcome of the state. It is fitting that there should be a welcome extended to you by the Massachusetts Horticultural Society, which lives within the limits of the City of Boston.

So it is my privilege to extend to you this welcome, and for that Society and a thousand members I heartily bid you welcome not only to this building prepared for you by such meetings, not only to all the rooms in the building, but also a welcome to our great library, which has been so commended, and truthfully, by your President. We are proud of our institutions. We are proud of our library, and on behalf of the Society I want to say that while you are here the Secretary of the Society will throughout the day, every day, be glad to show any of you and all of you any part of the library and explain to you the treasures of which we are so proud.

More than that, as my voice is a voice of welcome, I want to give you the welcome of our allied institutions, the Arnold Arboretum and the Harvard Botanical Society, which is quite well known to your President. I want to do more than that, and welcome you to certain things within the Commonwealth of Massachusetts which have not been referred to, but which, to my mind, are most important in the survey of the horticultural work of this country.

(Mr. Burrage's complete address will appear in the next issue of *GARDENER'S CHRONICLE*.)

Mr. Craig, calling on the next speaker, said: Quite a common phrase is that ladies will always have the last word. We have our program with that object in view today. The lady I am about to introduce to you is one very highly esteemed horticulturally in Massachusetts. She has done much of late years to improve our exhibitions as an exhibitor, as one who supports lectures on exhibitions, and as one who interests children in garden work, and as one who at Hillcrest Gardens helps to train boys in the cultivation of plants, flowers, fruits and vegetables.

I have much pleasure in introducing to you as the last speaker of the afternoon, Miss Marion Roby Case of Weston, Massachusetts, one of the trustees of the Massachusetts Horticultural Society.

MISS MARION ROBY CASE

Miss Marian Roby Case responded: I am very glad Mr. Craig introduced me as he did, because it gives me the opportunity to say to you practical gardeners what I felt very strongly all day Sunday. I have been over my own place with a thorough landscape gardener, because I realized that with the executive work that I had to do as Vice President of the Farm Garden Association, as a member of the Garden Club of America, which extends its greeting to you today, and as a trustee of the Massachusetts Horticultural Society that I was losing something which all of you men are getting, the practical touch of the working of the plants in the land. You are getting a familiarity with those plants which I want but do not always have the time to get, and so it is a great pleasure for me to be here today and tell you that you practical gardeners are getting something which we want.

The plan of the farm is, the boys come to Hillcrest the Monday after Bunker Hill Day, so they practically begin with Bunker Hill Day and end with Labor Day, when they read the papers connected with the work on the farm.

The lecturers for the season on Wednesday afternoon have been Miss Weatherback, who told the boys about the wild flowers of New England; David Fairchild, who was to have come, but on account of illness was unable to. Dr. Ferno took his place, and on Labor Day we received a package of twenty-seven wild flower seeds gathered in Nova Scotia from Dr. Ferno. Warren H. Mack impressed on the boys the beauties of the country in which they were living, showing them large, freehand drawings done by an Italian or Russian of the country in which they live. Mr. Loomis talked to them on writing, and William Gray, who was to have been here this afternoon, spoke to them on the cultivation of out-of-door roses, giving such practical advice as we have been trying to follow, because he showed the beautiful long-stemmed roses which he had been unable to grow out-of-doors.

Professor Thompson, Director of the Agricultural Experiment Station in Lexington, Massachusetts, spoke to them of the chemistry of the air as related to plant life, and the impression that talk made on the boys was evidenced by the observation papers which afterwards came in. Elbert R. Jacks spoke of nut growing in New England. Dr. Warehead, who has come into prominence this Summer in research work which he has been doing among the Indians, spoke to them about the American Indian past and present. Professor McKaye, Director of

the Blue Hill Observatory, spoke to the boys on rain makers.

Miss Elizabeth C. White spoke on the cultivation of bluebells. Robert Murphy, of the Department of Ornithology of the Museum of Natural History, New York, spoke on birds and their ways; and then on Labor Day the boys read their papers.

The program of the boys' work through the year is—on Mondays they read observation papers; on Tuesdays they have a lesson on the growth of plants. Mr. Stanton has the boys in charge. Wednesdays they have a series of lectures. On Thursdays they write reports of the lectures. On Fridays I have them in study hour, and on Saturday, being a half day through July and sometimes in August, they have an automobile ride to some place of interest.

One Monday afternoon I asked the boys to write on what they had learned at Hillcrest Gardens, and I brought one of those papers in to read to you this afternoon, for I felt that this would give practical evidence of what the boys have learned and of our system.

Several papers written by the boys at Hillcrest, each one showing much interest and earnestness in the work they were engaged in, were read by Miss Case.

GENERAL DISCUSSION

Mr. Craig announced: You will find underlying the paragraph of Miss Case's very interesting talk the word "discussion."

We usually have a little discussion after the speakers of the afternoon are finished. We had in New York last year and I would be glad now to hear from any one who has a few remarks to make on Miss Case's talk or anything else that you heard this afternoon. Who will be the first?

Mr. Mackintosh replied: It seems to me that there has been a considerable amount of talk altogether on a false basis. You tried to give the impression that there is no such thing as an American boy who is interested in gardens. Now we have a complete denial of the facts in what the lady has said.

Now you horticulturists of Boston and Massachusetts, don't you think this would be a good opportunity for you to take these boys after the work in this garden, into your large gardens and finish the article?

Miss Case, in reply to Mr. Mackintosh, said: It may be interesting for you to know that Friday morning is the day that I am with the boys in study hour. I had the twenty boys together and I asked those boys how many of them expected to stay on the land when they were men, and twelve of them told me that they hoped to stay on the land.

George F. Stewart remarked it may be interesting to tell the members about the approximate ages of the boys.

Miss Case: The prize for the best paper written for Labor Day was given to an older boy, who wrote two of those papers which I have just read to you. The other prize was given to a boy, about one of the youngest on the place, a boy not more than twelve years old who had written an excellent paper on currants. They had considerable discussion about the papers. The prize for the best observation papers written by the younger boys was also given to one of the youngest of the boys in that second class.

This year we had to divide the boys into Class First and Class Second rather than into older and younger boys, because in the second class of boys who are on the farm for the first time this Summer there were some older boys, a boy of sixteen being among those boys.

COMMITTEE TO EXAMINE PLANTS

Mr. Craig appointed, as a committee to examine the plants, Mr. Rust, Mr. Michie and Mr. Jas. Stuart. The meeting adjourned until eight o'clock in the evening.

TUESDAY EVENING MEETING

At the meeting at Horticultural Hall on Tuesday evening an intelligently delivered lecture, illustrated with beautifully colored slides was given by Edward I. Farrington on the fine trees and shrubs that are to be found in the Arnold Arboretum, which when propagated will be a great benefit to Horticulture. The lecture was a most instructive one to the gardeners present, all of whom enjoyed it immensely.

WEDNESDAY MORNING SESSION

The meeting was called to order at 9:20 A. M., Robert Cameron, President, in the chair.

Martin C. Ebel, the Secretary, then presented his report.

SECRETARY'S REPORT

THE most important accomplishment of the association during the year has been the inauguration of the course for training young men in the gardening profession, in co-operation with the Massachusetts Agricultural College, whereby young men are to

receive their theoretical training at the college and practical experience on private estates. As this subject is to be brought up for general discussion during the convention, I shall not go into detail at length here. This movement is regarded as a great step, not only by the members of the profession of gardening, but by other interests allied with horticulture, as it is the first course of its kind ever introduced in this country.

Two new branches have been established during the year. One at Boston and one known as the Western Pennsylvania Branch, taking in Sewickley and surrounding territory. Others at present are in the course of organization.

Contrary to the general expectation of a year ago there has been no great demand for efficient gardeners to fill worth-while positions this year. It was anticipated that due to the many properties which had been purchased during the past two or three years, development work would be started on many of them. But such has not proved the case. Estate owners are still waiting to learn how much the Government is going to allow them to retain of their income before increasing their expenditures. The Service Bureau will be more fully covered in its special report.

There has been but little progress made in the campaign against the sign boards defacing the landscape along the highways, although the association has secured numerous communications from civic and other organizations and from individuals expressing their interest and their desire to help. When they were advised that interest in the campaign meant work, their interest apparently waned. Several important organizations in their reports, however, agree with the association that the only way to accomplish anything in this direction is through educational lines to arouse public sentiment and that attempts to curb the sign board nuisance through legislation would be futile. In the meanwhile, the sign board industry is increasing by leaps and bounds.

Nothing of importance has developed on the question of Quarantine No. 37 as far as the association is concerned. A meeting was held in Washington, presided over by Secretary Wallace of the Department of Agriculture. As good politicians, the Washington representatives of the Government agreed that they were desirous of doing what they could to meet with the desires of all interests. Secretary Wallace also stated that the horticultural interests would hear from him within six or seven weeks as the matter would have his personal attention. Many more weeks have elapsed, but no word has come from him. A prominent grower who has followed the Quarantine No. 37 situation and been an attendant at all the meetings, recently remarked to me that he realized that the only way anything will ever be accomplished is by educating the public what this quarantine deprives them of, and the injustice of barring many of the plants. The horticultural interests are so divided and many so uncertain of their position that it will be a difficult matter to bring enough of them together to influence the "powers that be."

As a result of the Cleveland convention in 1919 when the school garden committee was appointed at the request of the Board of Education of that city to go over the ground and make recommendations to extend the school garden work, a complete new range of glass at a cost of some \$40,000 was contracted for this year. O. M. Eastman, supervisor of the Cleveland school gardens, gives the association's committee full credit for the extension of school garden work in Cleveland.

The association lost 10 members through death, 21 members through resignations, and has taken on 65 active and associate members and 10 sustaining members. The association is suffering from lack of co-operation on the part of its members at large. We come together at the annual conventions, which year after year prove more successful, become aroused and loaded with "enthusiasm," pledging ourselves on our return home to take off our coats and boost for the N. A. G. Somehow or other the enthusiasm is lost before we reach home. Every member, with a little effort, could interest one or more fellow gardeners to become members and also their employers as sustaining members. We have received letters from estate owners asking whether they were eligible for membership, and wondering why they had not been invited as they had observed the names of good friends on our sustaining membership list. This individual effort on the part of each member would increase the membership roll and the interest in the association in the field of gardening.

M. C. EBEL, Secretary.

MR. MACKINTOSH: I think it is the custom in all organizations, when necessary, to take notice of deceased members. And I think it would be quite in keeping with the feeling of this Association if the Secretary were instructed to write a letter of condolence to the relatives of our deceased members.

MR. CRAIG: At other conventions they have committees appointed to draw up suitable resolutions. That ought to be done here. The committee draws up a set of resolutions to cover all the deceased members. It ought to be done at each convention. I make a motion that the Chair appoint a committee of three to draw up suitable resolutions to forward to the kin of the deceased members.

The motion was seconded and carried.

THE PRESIDENT: You will now listen to the Secretary's financial reports.

The Secretary then presented his financial reports, one dated October 10, 1921, the other September 1, 1922, which follow.

SECRETARY'S FINANCIAL STATEMENT

NEW YORK, N. Y., Oct. 10, 1921.

RECEIPTS

Cash on hand, August 20, 1919	\$ 161.40	
Cash on hand, Sept. 10, 1920	620.43	
Received for delinquent dues	22.00	
Received for 1920 dues	428.00	
Received for 1921 dues	3,626.00	
Received for life memberships	350.00	
Received for 115 sustaining memberships.....	1,150.00	
Received for Service Bureau Fund	70.00	\$6,427.83

EXPENDITURES

MONTAGUE FREE, Treasurer.

BOSTON, Mass., Sept. 12, 1922.

We have completed our audit of the accounts of your treasurer up to September 1, 1922, and are pleased to report that we find the statement as rendered above to be correct.

JAMES STUART,
THOMAS W. HEAD,
HENRY E. DOWNER,
Auditing Committee.

Mr. Downer then presented the report of the Service Bureau, which follows:

THE WORK OF THE SERVICE BUREAU

THE Service Bureau has not been as active this year as in previous years due, of course, to the fact that there has been a small demand for gardeners of the efficient type. There are always more or less calls for what might be termed the mediocre gardener. When such inquiries come, the Service Bureau does not attempt to fill them, but attempts to educate the estate owners by apprising them what really constitutes a true gardener. We have at times been ridiculed for endeavoring to present gardeners as of a professional rank. On the other hand, on a number of occasions, we were successful in interesting the estate owners to try a more efficient gardener than they had been accustomed to. The reports which come to us have been that the experiment proved most satisfactory.

Early in the year there were quite a number of inquiries for highly efficient men to superintend the development of new places, the positions to be filled this Spring, but in each case when Spring came, the owners had reached the decision not to go ahead until general conditions are improved.

There is no doubt that the Service Bureau is the most difficult of all the departments of the association to operate. Those who have anything at all to do with the operation of the Service Bureau show no favoritism but select the men whom they believe are best fitted for the positions, and that they are not far wrong in their judgment is substantiated by the splendid record that the Service Bureau has established among many estate owners.

The association is eager to conduct the Service Bureau on the highest plane possible. If it can be improved, and as stated at previous conventions, if there is any member who has constructive suggestions to offer, the association will appreciate receiving them.

M. C. EBEL.

THE PRESIDENT: You have heard the reading of the Service Bureau report. Are there any remarks? This is a good time to discuss things if you have anything to say.

MR. MACKINTOSH: It seems funny that no one wants to say anything, that no one has any kick. I rise to move the adoption of the report as sort of an introduction.

I did happen to be in the Secretary's office now and again up until five months ago, and I can assure you gentlemen who live a distance away that it is no joke what the Secretary tells you about people coming in. In fact, when I am in the neighborhood I run in to say, "How are you?" and when he is busy I go right out.

As to the jobs, that is a thing you can't help. You know every man thinks himself about the best there is, better than Mc-Phearson or John Thompson, and he don't see why he shouldn't get the job, and so on. But I think that as far as the Secretary's report goes, all the men that have been placed through the Bureau have given satisfaction. I don't think that the Association could expect anything more.

THE SECRETARY: Mr. Chairman, I would like to say that this would be a good time to make suggestions of how the Service Bureau ought to be conducted. The criticism pretty generally is that it is not conducted right. When they come to me and say that it isn't conducted right, I ask them how they would do it, and they say, "I don't know, but you are not doing it right. You are not satisfying the gardeners."

Now, I am conducting the Service Bureau to the best of my ability, as far as I know. Every convention we ask for suggestions and ideas, but we don't get them.

The report was accepted as read.

As there were no resolutions, the next business in order was the nomination of officers for the year 1923.

NOMINATION OF OFFICERS

Mr. Michie nominated John Barnet for President.

The nomination was seconded and motion made nominations close. Carried.

Mr. Head nominated John H. Francis, of Cleveland, for Vice-President. The nomination was seconded.

Mr. Stewart nominated William Gray, of Newport, R. I. The nomination was seconded.

Moved and carried, nominations be closed.

Mr. Head nominated M. C. Ebel as Secretary.

The nomination was seconded and moved that it be closed. Carried.

Mr. Stewart nominated Montague Free for Treasurer.

The nomination was seconded; moved that it be closed. Carried.

THE PRESIDENT: There are now five Trustees to be nominated for the year 1923.

Mr. Ebel announced that, according to the charter of the Association, it is compelled to nominate three Trustees for the State of New Jersey, and nominated Mr. Head, Mr. Mackintosh and Arthur Smith from New Jersey as the New Jersey members and Mr. Cameron as one of the two Trustees-at-Large.

Mr. Stuart nominated Andrew L. Dorward, of Newport.

Moved the nominations be closed. Carried.

The President announced the next thing on the program was the consideration of the meeting place for next year.

Mr. Donald proposed Pittsburgh.

Mr. Barnet presented a personal invitation from the branch in Western Pennsylvania.

Mr. Stuart moved the nominations be closed.

THE PRESIDENT: It has been moved and seconded that the nominations close. All those in favor will please signify by saying, "aye"; contrary, "no." It is a vote.

Under the head of New Business, the President inquired: Has any one anything to bring up before the meeting at this time?

MR. DOWNER: I make a motion that a recess be taken. The motion was seconded. Carried.

RECESS

The President called the meeting to order to consider New Business.

NEW BUSINESS

MR. DOWNER: The Board of Directors recommends to the convention here now assembled that an honorarium of \$1,000 be paid Mr. Ebel.

MR. CRAIG: Mr. President, I don't know whether the members all heard that or not. It was that the Board of Directors recommended that the convention award an honorarium of \$1,000 to Mr. Ebel for his services.

The recommendation was seconded by Mr. Head. Carried.

MR. DOWNER: The Board of Directors also recommends that from now on the Secretary shall receive a salary of \$3,000 a year, to be paid in monthly instalments; the Service Bureau as now conducted, as a separate unit, to be discontinued. The Secretary's salary shall cover office rental, clerk hire, telephone and telegrams, postage, traveling expenses and all other incidental expenses connected with the office and work of the Service Bureau.

MR. HEAD: Mr. Chairman, for the benefit of the members assembled—some perhaps did not hear well enough and perhaps do not realize what we are trying to do—the point of issue is to get the Association on a financial basis. The Association has been in existence a good many years, and up to date there has been no financial standing; that is to say, we haven't been put on a good financial basis.

Now, the main thing is to get the Association on a good financial basis, and the first thing to do is to have your Secretary paid a sufficient salary so that he can conduct the business in a businesslike manner.

Then, the Board of Directors has also thought over the Service Bureau, and from what we could gather the Service Bureau has been a bill of expense to the Association, without getting the results that we thought we would. So, therefore, we are going to cut out the Service Bureau as it is now being run, and will leave the Service Bureau end of it with the Secretary, to carry on as he sees fit. That is to say, should a position come in, should a lady or a gentleman ask for a gardener from the Service Bureau, it would be the Secretary's business to assist that party in getting a gardener from the National Association, but not to run the Service Bureau the way we have been running it, at such a big expense without getting very much for it.

The main thing is to get the whole thing down on a good financial basis, so that we know where we are at. It is like any other business. There is the reason for the recommendation, and I hope, fellow members, that you will see it in the same light that we have seen it. We sat down and talked it over. It isn't only today that we have talked it over, but we have been considering it for some time; but we got together today and formulated this plan, and we think that \$3,000 ought to be enough to carry the thing along.

MR. MACKINTOSH: The only thing about that is that the members of the Association who have been talking about this must not get away with the idea that the Service Bureau is to be eliminated, because it will not be, and the same services that were given before will be given from now on, and Mr. Ebel, as Secre-

tary, will use his good offices as Secretary of the Association the way he used to use them as Secretary of the Service Bureau. It is a case of amalgamation. We are going into a trust. Nobody is to go away with the idea that there is to be a discontinuation of the Service Bureau, because if any of you want any advice or want any men, the service will be just exactly the same as heretofore, only not as a separate thing.

The recommendation was favorably adopted.

QUARANTINE 37

MR. CRAIG: Mr. President, you, in your Presidential address, like a wise man, changed your mind from last year. Last year you got on the floor and you applauded Quarantine 37. In your Presidential address you thought it was a great iniquity. A wise man changes his views, and this shows that you are one.

I think this Association ought to go on record again as opposed to Quarantine 37 as at present on the statute book. We know that a good many commercial interests applaud it for certain selfish reasons. The body of men which formed the Federal Horticultural Board, composed of etymologists, bacteriologists, and others, were put there to bar out injurious insect pests and diseases. They formed themselves into a Tariff Board to keep out all products from abroad that we need here in our gardens. Now the commercial interests, in a large measure, applaud that because for some of the material they have on hand they can get handsome prices from the ultimate consumer, and therefore, as your President said, the prices have been immensely increased to the buyer, the amateur, the gardener, and we ought to go on record as demanding a moderate modification of Quarantine 37 as at present on the statute book.

It is unfair to the great horticultural interests of America that they should suffer because five men were put there to keep out insect pests and they formed themselves into a tariff commission, and because the bulk of the nurserymen, and some florists, who are just as bad as the nurserymen, think that they ought to bar all foreign products and by doing so get a higher price for commodities here at home.

It is not fair at all, and we ought to go on record as a National Association as demanding a modification of Quarantine 37.

A lively and most interesting discussion arose, following Mr. Craig's remarks, in which a number of members participated, all against Quarantine No. 37, and many points not heretofore brought to light were presented, showing the unfairness and unreasonableness of this Act. Space will not permit publishing the many experiences related. They will, however, be handled as a separate subject in the next issue of THE GARDENERS' CHRONICLE. The principal points of the discussion were that the Quarantine was a tariff protective rather than a preventative against insect pests and diseases in this country; that many nurserymen were taking advantage of the situation to place prohibitive prices on their stock, and that, contrary to the claims of the Federal Board that many of the barred plants have already been propagated in this country, the reverse is the case.

Mr. Craig, who took an active part in the discussion and in his usual forceful manner, whenever the issue is before him, condemned many of the practices now being resorted to under cover of Quarantine No. 37, continued that the Association should at least ask the Federal Horticultural Board to import, under careful scrutiny, new, rare and desirable plants, without bonds. "You and I," he said, "have boys who perhaps want to follow this profession, but we want them to obtain new, rare and interesting material. You think we can propagate everything. We cannot." Mr. Craig moved that the National Association of Gardeners go on record as demanding a fair adjustment of Quarantine No. 37 to permit amateurs to introduce new, rare and desirable plants without having to give bonds for same, after careful inspection.

The motion was seconded and carried.

RESOLUTION OF WESTERN PA. BRANCH

Mr. Barnet submitted the following resolution which was approved by the recently organized Western Pennsylvania Branch of the National Association of Gardeners:

"The members of this branch are pleased to note the tendency for closer co-operation between our Association and the various Garden Clubs throughout the country.

"We feel that this cordial relationship should be still further encouraged and, with this object in view, bring before this assembly for its consideration and approval the following suggestion:

"That the Association engage a competent lecturer, who shall appear before these Garden Clubs, presenting our aims and objects, soliciting still closer co-operation in matters that affect the mutual welfare of the members of the various bodies concerned.

"We believe that a campaign along these lines, or similar lines, would very materially enhance the prestige of our Association."

(SIGNED) COMMITTEE, WESTERN PENNSYLVANIA BRANCH, NATIONAL ASSOCIATION OF GARDENERS, MARCUS CURRAN, JOHN CARMY AND HENRY GREENE.

While it was generally agreed that the resolution submitted by the Western Pennsylvania Branch contained some excellent ideas and that it was most desirable to secure as much co-operation as possible between the Garden Clubs and the Association, nevertheless, it was questioned by some whether the Garden Clubs, as a whole, would really accept the proffer of having the Association provide a free lecturer to speak on its aims and purposes. The Garden Clubs, it was said, already had a long list of lecturers from which they chose and paid well for. It was also suggested that the National Association of Gardeners is hardly in a position to stand the expense of what is proposed in the resolution. The experience is referred to when, in the earlier days of the Association, printed lectures were distributed among the Garden Clubs, and they were welcome, but after a while interest in them ceased. One of the arguments were that something for nothing is never appreciated and that the Garden Clubs are always willing to pay for lecturers. It was finally moved to accept the resolution and lay it on the table. Carried.

President Cameron appointed as a committee to draw up a resolution on the deceased members Mr. Craig, Mr. Barnet and Mr. Downer.

On the committee to draw up final resolutions, Mr. Michie, Mr. Mackintosh and Mr. Stewart were appointed.

The meeting then adjourned to meet again in the afternoon.

ADJOURNMENT

WEDNESDAY AFTERNOON SESSION

The meeting was called to order at 2:25 P. M., Robert Cameron, president, presiding.

THE PRESIDENT: Will the meeting please come to order? The first business for this afternoon is the action on amendments to the By-Laws, which Mr. Downer will read for you.

Mr. Downer then read the amendments to the By-Laws which were suggested relative to the Reserve Fund.

We, the undersigned Branches of the National Association of Gardeners, being of the opinion that the increase in the life membership dues will act as a deterrent to the increase of the Reserve Fund and also being of the opinion that this Fund should be materially increased each year, do respectfully petition that the following amendments be made to Article VII of our By-Laws.

ARTICLE VII

Change Section I to read:

Section I. All moneys collected from life-membership dues shall be placed in the *Reserve Fund*.

Add Sections II, III, IV and V to read:

Section II. Ten per cent of all moneys collected from active, associate, and sustaining membership dues shall be placed in the *Reserve Fund*.

Section III. All investments of the Association shall be considered a part of the *Reserve Fund*.

Section IV. Yearly interest accruing on the *Reserve Fund* shall be applicable to the fund, or the whole or any part of said yearly interest may be extended for specified purposes on the advice of the Trustees subject to the approval of the Association at its Annual Convention.

Section V. The principal of the *Reserve Fund* shall be held intact.

Approved by the Newport Branch, March 22, 1922.

Approved by the Boston Branch, June 30, 1922.

Approved by the St. Louis Branch, September 1, 1922.

NEAL MCCALLUM made a motion that the amendments just read by Mr. Downer be added to the By-Laws. Seconded and carried.

Mr. Downer then read the amendments to the By-Laws for the Local Branches.

ARTICLE VIII

LOCAL BRANCHES RULES AND REGULATIONS

Section 1. The object of the local branch is to establish a closer contact between the individual member and the main organization, and to spread a better knowledge of the aims and objects of the National Association of Gardeners among non-member gardeners and others interested in Horticulture.

Section 2. Six or more members of the National Association of Gardeners may organize and form a local branch designating the branch after the district in which they are located.

Section 3. On organization each branch shall appoint a chairman and a secretary, and notify the secretary of the National Association of Gardeners of their action giving the names of the officers and the number of members composing the branch.

Section 4. Meetings shall be held as the members may de-

termine and may be of an informal character. Non-members present may enter into discussions but cannot vote on any question.

Section 5. Each branch shall be entitled to send a delegate to the Annual Conventions of the Association. Any branch unable to send a delegate owing to distance or other causes may be represented by a member of another branch.

Section 6. A delegate on arising to address the Convention shall preface his remarks by stating the name of, and the number of members in the branch he represents.

Section 7. Applications for membership in the National Association of Gardeners coming from a district in which a local branch is organized must have the endorsement of that branch.

Section 8. It shall be the duty of committees appointed on important matters at the convention to ascertain, through correspondence with the secretaries of the local branches, the sentiment of the members on the matter in question and base their reports on the consensus of opinion so obtained.

Approved by the Newport Branch, March 22, 1922.

Approved by the Boston Branch, June 30, 1922.

Approved by the St. Louis Branch, September 1, 1922.

W. N. CRAIG: There is a diversity of opinion regarding one or two clauses here. Some members have the idea that a delegate going from a branch to a convention represents the full power at that convention in voting, and this is something that we cannot possibly tolerate.

A member going, say, from Newport to the convention and speaking for forty or fifty members, should not be delegated to cast forty or fifty votes. We cannot tolerate that. We ought to give them some voting power. What it is, is for us to determine, but it cannot be the number of the members in that branch.

MR. ROGERS: I don't see why a member should be misled to think that they have sixty or seventy votes from any local branch. There is nothing in these By-Laws to determine that, as Mr. Craig says, but my opinion of it was when it came up in the local branch in Boston, that a member if delegated when he rose to speak in a convention, would preface his remarks by stating how many he represented.

For instance, if a question came up in a local branch which was to be debated at the convention, when the delegate from that local branch got up to speak he would tell whether that was a unanimous vote of the local branch or if it was divided, and if so, how many were for it and how many were against it.

My opinion was that it would have a tendency to influence the members in the convention as to what the majority thought of that issue, and I think it is a good thing in that sense. I don't mean that he should get away with sixty or seventy votes, I think that is an outrage.

MR. STEWART: I think it would be advisable on our part to decide right away how much power we really should give, the percentage according to the numbers in a local branch. I feel that local branches ought to have a little more power than they have, and by giving them a percentage of the number, as has been argued by several of our members privately, it would increase the interest and get some outsiders to get hold of the affairs of the Association.

MR. DOWNER: Mr. President, this point occurred to me: Suppose you had a local branch of forty members and you decided, we will say from a talking standpoint, that you would give one delegate to ten members, therefore, that branch would be entitled to send four delegates.

Suppose the local branch discusses some subject and the opinion is not unanimous. You may have thirty for it and ten against it in the branch meeting. What would you do about representing the majority? You couldn't send four delegates here if there were ten against it.

MR. BARNET: If four delegates choose to come here of their own will they could still cast four votes.

MEMBER: Is there anything in those regulations regarding voting? We are not discussing that. The article as read has nothing to say about voting.

THE PRESIDENT: This has come from the outside and we want to get it straightened out.

MR. STUART: I have thought this over quite a little. What I came here to listen to today was what the branches already formed want. What vote do they want? I imagine what they get today is pretty nearly nothing.

What I would like to see is just a little power for the branches, between the branches and the Board of Directors, say the branches would recommend something to the Board of Directors to work on, and the Board of Directors would take it up and recommend it to the annual convention. Give them a little authority to do something, not the power to vote. I think that voting power isn't of much count when it comes to the final analysis. Give them some interest in the Association. I think if the Directors would write to those branches and ask for suggestions regarding the Association from time to time, ask those branches what they have been doing in the last quarter, what that particular branch has been

doing and if they have any suggestions to offer us as the Directors of this Association to go onward,—that, in my opinion, is the whole thing, not that voting power, that is too much like politics.

MR. DONALD: What was the origin of this thing? What started up this thing? Did the branches ask to get a vote in the convention whether they were represented or not?

THE PRESIDENT: There are only going to be National Association members belonging to the branches, consequently they are a voting power if they come here.

MR. DONALD: What do you mean by saying that you give them so much per cent?

THE PRESIDENT: That is, supposing a club in Chicago with quite a number of members had only one man coming from that local branch to the convention. Some have read this thing as meaning that all of the members belonging to that branch could vote. If they had fifty members they could cast fifty votes, consequently it would swamp our meetings. We don't believe in that and we are talking this over to see if we can get a better way out of it.

MR. STUART: The trouble today is that the branches don't have enough authority in the conventions. They ought to have some say in the working of this. If they had some authority, some connection with the Board of Directors in the working of this Association you would have more interest in the whole thing. I was told that the Nassau Branch has almost out-functioned just because there is no connection between them and the working of this Association. They are absolutely almost independent. If we could establish some connection either between the Board of Directors or the Association and the branches, it would give them something to go by. Let them recommend something to us. Listen to their voices by all means in whatever they have to suggest or say, otherwise they cannot be fully represented at these conventions.

MR. STEWART: I would like to ask the last speaker, for instance, if any issue came up in the local branches and it was accepted by three or four of these local branches, and if the Directors see fit to throw that down, would it be their place to do so?

THE PRESIDENT: It would come up at the annual convention where it would be settled. Is there any further discussion?

MR. FORBES moved that the amendment be adopted. Seconded and carried.

THE PRESIDENT: The next thing to come up is a discussion on the Two-Year Course for Gardeners at the Massachusetts Agricultural College, opening September 27, 1922. I wonder if Mr. Downer wouldn't read about this course at Amherst. Probably then you would have a chance to discuss it better.

MR. DOWNER read an outline of the course to be given at Amherst, September 27, 1922.

THE PRESIDENT: Are there any remarks?

MR. McCALLUM: I think it is the opinion in Europe that a man should learn to work with his hands first. The boys who go from high school to college are afraid to get dirt under their finger nails, and they don't take kindly to work. I think it is better that men should become journeymen gardeners before they take this course.

THE PRESIDENT: You will notice that they have to have two years' experience before they begin this course.

MR. CARTER: I see that at the end of this training, it says they will be examined by a Special Board. I am looking for information. I would like to know what kind of a special board would be selected.

I am reminded of a letter which I read in the CHRONICLE some time ago by one of our worthy members who said that he would venture to think that if this examination for gardeners was established and adapted on the same lines as in Europe, that our college professors who were teaching horticulture here in this country would fail to pass an examination similar to that conducted in Great Britain, for instance. If the ones teaching horticulture in this country wouldn't be capable of passing the examination, it is a question in my mind as to who would be capable of examining the students.

THE PRESIDENT: I don't quite agree with you. I think that there are men as capable in this country as there are in Europe today.

MR. CARTER: I was looking for information as to who the Special Board would be and who would have the duty of appointing this Special Board.

MR. DOWNER: I think it is clear in the pamphlet. It states that at the end of their second year of theoretical training, if successful, they will receive a certificate from the college, based, of course, on the theoretical training. From this point they enter upon an apprenticeship of two years, supervised by the National Association of Gardeners. That is the practical work.

At the end of this time they will be examined by a Special Board, and, if successful, will receive the diploma of the National Association of Gardeners. That special board might be made up of members of the Gardeners' Association and the authorities at Amherst. It doesn't say anything about a set examination.

THE PRESIDENT: I should like to tell you the story of a boy I have working for me now and whom I wish to take this course. He came from high school and he had been there two years. I found out that he knew a good deal about vegetables. I said, "You are quite interested in this work, aren't you?" He said, "I have taken all my studies in school on gardening." I said, "You are eligible for this course at Amherst." So I asked him if he wouldn't consult his father and the superintendent of schools about going there. He came back and said that they both thought well of it.

One morning I said to him, "You must remember that it will cost you in Amherst from eight to twelve dollars a week." He said, "I am prepared. I have a thousand dollars, in fact, I have two thousand dollars." That boy has just passed his seventeenth birthday. I said, "How did you make this money?" He said, "I had a garden and grew vegetables. One year I sold \$250 worth of vegetables. My father said that if I would save five hundred dollars he would double it. Since that time I have saved another thousand."

I paid that boy sixteen dollars a week, and that is what they expect to get, those going to college—or perhaps twelve dollars a week.

MR. CRAIG: I want to tell you my experience with college boys. I think they are better in every way than the boys without training, far better. They are quicker to learn, their brains are clearer, they are more studious and they are going to make better men.

The same applies in our profession. The men who are going to follow us are going to be a very different type of men. And if we are to build our Association up and get the type of men that we need, we must help to boost this college course. It is gotten up with the sincere hope to elevate our profession and give us a type of men we need to build up a better type of horticulture in America. I am hoping to send my boy there and we want you to send boys there to help us.

I think there is a small body of three men qualified to pass on those boys in our profession, don't you? I am not going to be in it much longer, but I hope to see one or two of my boys follow in the line for a time, at least. I want them to have the credit of an education which was denied to us when we were small. Don't belittle our profession, but help us in this course, help build it up and help build up your Association at the same time.

MR. ROGERS: I was interested in the lectures at the Garden and Floral Club this last Spring when this issue came up at the preceding meeting, and in our minutes of that meeting Mr. Craig claimed that bigger and better brained men would come out of that college course.

At that same lecture we had a Professor from Amherst, Professor Thompson, and I think some of you present remember how he complimented the men who served an apprenticeship across the water, and he was a college professor himself.

The men who served an apprenticeship across the water in the old way, it seems to me, are good growers and good men, but they haven't got the flow of language that a college graduate has.

If you think this is going to be a benefit to the boys, try it. I sometimes think it is going to be a success.

MR. BRYANT: I would like to say a few words. I think that this is worth trying out if it is given the way it is stated in this program, giving a blend of the theoretical with the practical, and I think that probably it would be a mighty good thing.

I took a short course at Amherst just for the pleasure of it and I had a very enjoyable and educational time there. I think that if everybody could do the same thing, it is surprising what enjoyment could be gotten out of it. I think that we all feel that the more education we get the better off we are and the better off the world is for it, but I do think, as Brother Mackintosh says, it depends upon the boy or the man.

MR. STUART: The members seem to think that this is a new move. It might be new to the National Association of Gardeners, but I remember about twenty-two years ago when I started looking for a head job in Boston, they advised me there were only head jobs for those who took a college course. That was twenty-two years ago. What do you find the condition today?

I have been here for a week and around to the best places in Boston, some beautiful places that have fine gardeners and a haven't seen a college graduate on one. Is that an indication that the college man will be successful in the future?

THE PRESIDENT: I should like to say to Mr. Stuart that this is the first time that a course like this has been given in the United States, consequently, he couldn't see very many who took a course like this to get gardeners in the profession. So that in the future, if he comes back another twenty years from now, I think he will probably see some of these men around.

MR. STUART: Wasn't that same thing available twenty years ago?

THE PRESIDENT: No, sir. Nothing like it has ever been given in this country, and we ought to feel proud that our Association is the first to take this thing up and is starting a course like this. I would like to have it adopted.

MR. MACKINTOSH: By all means. I thought that was

going to pass that stage long ago. Why shouldn't it? It is a step in the right direction. There are some men who are spoiled by education, but not very many.

I have much pleasure in moving the adoption of all that has been done by the college people and by the people representing you here as your Directors, and so on.

THE PRESIDENT: It has been moved and seconded that we have a rising vote in adopting the rules and regulations of this course at Amherst College for Gardeners. (The delegates all arose.)

I am glad it has been passed. It is one of the finest things we have done in this organization, and I am glad that I am President here during this term.

THE PRESIDENT: The next matter of business is the Election of officers. I will appoint Mr. Downer, Mr. Bryant, Mr. Finlayson, Mr. Stewart and Mr. Donald as Tellers.

THE SECRETARY: One ballot can be cast for the President, Secretary, Treasurer, and for Mr. Head, Mr. Mackintosh and Mr. Smith. You only have to ballot on the vice-president and two trustees at large. Only active members are entitled to vote. Associate members have no vote.

The candidates to vote for: The candidates for trustees at large are Mr. Cameron, Mr. Fisher of Ohio, Mr. Johnson of Pittsfield and Mr. Dorward of Newport.

MR. CRAIG: Moved the Secretary cast one ballot for President. Seconded.

THE PRESIDENT: The Secretary has cast one ballot for President. Mr. John Barnet is elected President of this Association for the next year.

THE SECRETARY: The candidates for Vice-President are Mr. Gray of Newport and Mr. Francis of Cleveland.

MR. CRAIG: While the tellers are counting the ballots I move that the Secretary cast one ballot for the Treasurer. Seconded.

THE PRESIDENT: The Secretary cast one ballot for Treasurer. Mr. Montague Free is elected Treasurer.

MR. MACKINTOSH: I move that Mr. Craig cast one ballot for Secretary. Seconded.

THE PRESIDENT: Mr. Craig has cast one ballot for Secretary. Mr. Ebel is elected our Secretary.

MR. MICHIE moved that the Secretary cast a ballot for the three trustees from New Jersey, Mr. Mackintosh, Mr. Head and Mr. Smith. Seconded.

THE PRESIDENT: The Secretary has cast a ballot for the three trustees from New Jersey, and these men are elected.

THE SECRETARY: We have to vote for two trustees. The following nominations have been made: Mr. Cameron, Mr. Fisher of Ohio, Mr. Johnson of Pittsfield and Mr. Dorwood of Newport. We have to vote for two.

MR. DOWNER: Mr. President and Gentlemen, the result of the balloting for Vice-President is, Mr. Francis 27 votes and Mr. Gray 22 votes.

THE PRESIDENT: John H. Francis is elected.

MR. DOWNER: Mr. President and Gentlemen, the result of the balloting for two trustees is, Mr. Cameron 43 votes, Mr. Dorwood 25 votes, Mr. Johnson 19 votes and Mr. Fisher 18 votes.

THE PRESIDENT: Mr. Cameron and Mr. Dorwood are elected as trustees for 1923.

THE PRESIDENT: Will the Committee on Final Resolutions report now, please?

Mr. Stuart then presented the final resolutions as follows:

FINAL RESOLUTIONS

The members of the National Association of Gardeners assembled desire to extend their thanks and appreciation to all those who have contributed to the success and enjoyment of our annual convention here in Boston.

We specially desire to tender our thanks to the Massachusetts Horticultural Society for the privilege of the use of Horticultural Hall for our business sessions. Our thanks are also due to the various committees, under the able chairmanship of W. N. Craig, who have done so much to make our visit to Boston an enjoyable success, and particularly to the committee of ladies who have specially provided entertainment for the visiting ladies, and to the convention at large. And, further, to the retail florists of Boston and all others who have provided decorations for our convention.

Finally, we request that W. N. Craig send a personal letter of thanks to all who have invited us to visit their places.

COMMITTEE ON FINAL RESOLUTIONS.

Alex. Michie,
D. L. Mackintosh,
James Stuart.

THE PRESIDENT: You have heard the reading of the final resolutions. Are there any remarks?

MR. ROGERS moved they be accepted. Seconded and carried.

THE PRESIDENT: Will the Committee on Deceased Members report now?

The resolution on deceased members was then presented as follows:

RESOLUTION ON DECEASED MEMBERS

The members of the National Association of Gardeners, assembled in their annual convention at Horticultural Hall, Boston, September 13, 1922, wish to express their sincere sorrow at the loss their ranks have sustained in the deaths of the fellow members, Mrs. Manuel Rionda, George P. Wetmore, Robert Bottomley, Thomas Hatton, Robert Williamson, William G. Hasker, Frank P. Sladen, and A. E. Muchldorfer, and wish to express their sincere sympathy to the families and those near and dear in the loss they have sustained, a loss which we equally share.

Resolved, That a copy of these resolutions be forwarded to the families of the deceased members and spread on the records of the Association.

COMMITTEE ON RESOLUTIONS,
William N. Craig,
John Barnet,
Henry E. Downer.

MR. BARNET moved its adoption as read. Seconded.

THE PRESIDENT: It has been moved and seconded that the resolution be adopted as read. Carried.

Is there anything else that ought to be taken up?

MR. BARNET: Mr. Chairman and Gentlemen, I have great respect for Mr. Craig. He has announced the fact that he is about to depart from active membership, and while he has taken up business for himself we still have his advice and counsel as an associate, and I move here today that we give him a hearty rising vote of thanks; that is the least that we can do at this time.

THE PRESIDENT: It has been moved and seconded that we give a hearty rising vote of thanks to Mr. Craig.

The members all arose and applauded, and sang "For he's a jolly good fellow."

MR. CRAIG: Thank you very much, gentlemen.

THE PRESIDENT: Before we depart, I thank you for your attendance here. I am very grateful for the way you have attended to business during these last two days. We have done a good deal of business and we passed it through our hands very quickly.

I sincerely thank you for your attendance and for sitting so long today through these long sessions we have had.

A motion to adjourn will now be in order if there is nothing else to take up at this time.

MR. MACKINTOSH moved that the meeting adjourn. Seconded.

THE PRESIDENT: Let us adjourn.

ADJOURNMENT.

THE ANNUAL BANQUET

After a busy day at the business meetings on Wednesday, the members, with their wives, daughters and sweethearts, assembled in the banquet hall of the Hotel Brunswick promptly at seven o'clock, where they enjoyed not only a splendid menu provided by the Banquet Committee but also the addresses that followed, which supplied much food for thought from those of the speakers, who were more seriously minded and who dwelt on horticulture and its benefits to mankind and the opportunities that are presenting themselves to the younger men to take up this noble profession, while some of the others proved themselves most capable wits, keeping the gathering in an uproar, thus providing considerable mirth. The gathering, of about 135 members and ladies, was one of the most representative that has ever come together at a gardeners' banquet. It will live long in the memories of all those present.

Judge Charles W. Hoitt, who presided as toastmaster, certainly proved himself a past master, ever ready with witty and humorous expressions to keep the general good feeling of the banqueters alive. As he in turn introduced the speakers, he was found well fortified with some witticism that aptly fitted each one he called on.

President Robert Cameron reviewed the early history of the Association and contrasted the present four-day convention with the two-hour convention held in Boston in 1911. He expressed himself as especially pleased that the course for training young men in the profession of gardening at Massachusetts Agricultural College in conjunction with the Association had been adopted during his term of office, and made an appeal to the mothers to interest their sons in gardening, the oldest and noblest profession, and not to discourage them by commenting on their work in the dirt, for no gardener works in dirt, but in soil. He concluded by wishing all an enjoyable time during the remainder of the convention, and in saying he was proud to see so many ladies present.

John Barnet, of Sewickley, Pa., President-elect of the Association, responded by expressing his thanks for having the high honor of being elected President conferred upon him, and that he would strive to uphold the honor to his utmost, although he fully realized it would be difficult to surpass the records of some of his predecessors.

Thomas W. Head, of Red Bank, N. J., after some witty remarks, contrasted the present convention with those of earlier years and spoke of the previous history of the Association when he had held office as President and then as Treasurer. He also referred to the attendance of the ladies at the convention and the dignity they added to it.

James Stuart, of Mamaroneck, N. Y., endorsed what the former speaker said, adding that he, too, was well acquainted with the early history of the Association, in which he had held office as Treasurer. He referred to the prestige the Association enjoyed as a national organization and to its remarkable growth in the few years since he had been Treasurer.

Edward I. Farrington, of Boston, Mass., complimented the members on their connection with such a worth-while profession as gardening and that they should feel proud of the regard in which it is held. He referred to the course of training in gardening adopted by the Association as being a splendid move, and further congratulated the members on their success in having aroused the interest of the estate owners in their Association.

William Munro, of San Mateo, Cal., spoke of his observations in the East and commented most favorably on the Eastern scenery and the cultivation of plants and flowers. He particularly referred to the gladioli and dahlias, of which he said the size of those growing in the California gardens are many times larger than those he had noticed on exhibition at Horticultural Hall. He also spoke of the pleasure he was deriving from his first attendance at a convention of the National Association of Gardeners, and congratulated the members on their organization.

Mrs. B. Hammond Tracy of Wenham, Mass., responded to the remarks of President Cameron on behalf of the mothers and said that they would encourage the boys to take up the profession of gardening, but that the profession of gardening must be put forth as one of the fine arts and the boys impressed that if they made good there would be advancement in the profession of gardening for them and that they would be regarded as creditable citizens in their communities. Mrs. Tracy also referred to Mr. Munro's remark on the size of flowers grown in the Eastern part of the country and those grow in California, especially the dahlias and gladioli, and said that Mr. Munro had noticed the exact point for which the Eastern growers were striving, that is, to reduce the size of the enormous dahlias, to secure quality rather than quantity, and to produce such a size as can be more artistically and easily handled by women in their homes for decorative purposes.

John H. Troy, of New Rochelle, N. Y., spoke enthusiastically of the benefit that the recently adopted course for training young men would bring not only to the gardening profession itself, but to the country as a whole, for Mr. Troy stated that it was only by bringing a love of Nature and of the beautiful in the lives of the boys and girls of this country that the radical "isms" can be wiped out.

W. A. Manda, of South Orange, N. J., waxed eloquent in his reference to the profession of gardening and the great privilege it is to be a member of it. He said he cherished the early years of his life which he passed as an active gardener and considers it a pleasure to be connected with the organization of professional gardeners as an associate member. He compared the profession of gardening with that of medicine and law, stating that while the two latter professions prospered on the misery of the people, the gardening profession brought joy into their lives.

Joseph Manda, of West Orange, N. J., called to mind the early history of the Association, of which he is one of the oldest members, which he pictured as quite different from that of the Association of today. He referred to the training of gardeners of former days such as he secured in his youth and the many menial tasks that were the lot of the young gardeners to perform as compared to the present-day training advocated by the Association.

William Kleinheinz, of Elkins Park, Pa., called attention to the fact that he was the last President of the old Association and the first President after its reorganization, and that he was happy he had salvaged the name of the Association when he viewed the progress it has made in the years intervening as indicated by this year's convention. Boston, he said, is associated in his mind with his earliest gardening days in this country, and the first prize that he was awarded in America. He spoke amusingly of some of his former visits to Boston, which was relished by the New England members.

Mr. C. C. Sumner, of Summit, N. J., spoke of the gardeners in a jovial manner as others see them, but in a vein that made it quite clear that he did not agree with those who appeared to believe that there were any disabilities or worries attached to those who engaged in the profession. He also stated he did not agree with the impression created by the President that Boston was the first to welcome the ladies, for they had been attending the conventions for some years, although not in as large numbers as they appeared in Boston, an indication that the conventions are a growing attraction for the ladies.

John C. Smith, of Boston, Mass., spoke of the arrangements of the convention, the display of plants and the reception which a home ad-

vocated to so arrange the grouping of flowers that they will give ideas to the public on how the flowers may be adapted for home decoration. Under the present form of exhibiting, Mr. Wheeler said, the public gained merely a massed impression of the quantity and quality of flowers, and not the artistic use to which they may be put in the home. He sought the co-operation of the gardeners in having this new system of exhibiting plants and flowers adopted.

D. L. Mackintosh, of Alpine, N. J., immediately started his audience to laughter when he arose and continued to keep them laughing with his Scotch wit until the time when he took up the mission that was before him. He then referred to President Cameron's urgent appeal to the attendants to the convention that they be on hand early the next morning and that they must get together by 8:30 A. M. Mr. Mackintosh stated that this amused him immensely, for in New York and New Jersey a half day's work was usually accomplished before that hour. He said that the many gardener friends present at the convention, both visitors and local members, had decided they should do something to assist Mr. Craig, who was retiring from the ranks of the professional gardener to engage in the commercial field, so that he might be on time when he took up his new duties. He then turned to Mr. Craig and spoke in feeling words of the loss his retirement would be to the profession, and dwelt on the great work Mr. Craig has done in the past for the benefit of the cause. He stated he was sure, however, that Mr. Craig's interest in the gardener would not wane as he entered upon his new duties. He then produced a package which he handed to Mr. Craig, saying that he was about to present him with a gold watch and chain as a token of esteem from his many friends among the gardeners.

Mr. Craig, who was overcome and surprised, said words failed him to respond properly in accepting this gift from his friends. He could but say how much he appreciated their thought and regard for him and that they could feel sure that his interest in them would remain as staunch as it has ever been.

The banquet adjourned, following the singing of "Auld Lang Syne," led by Mrs. John Tonkin, of Chestnut Hill, Pa., who had favored the members and their guests several times earlier in the evening by rendering pleasing solos in a most charming and delightful manner. Throughout the evening the Ecker Orchestra furnished music, Mr. Ecker also delighting the guests with several favorite songs.

AUTOMOBILE TOURS TO FAMOUS ESTATES

Some fifty automobiles left the Hotel Brunswick at nine o'clock on Wednesday morning, covering some of the principal avenues and boulevards of the city of Boston to Revere Beach, "the Coney Island of New England" as it is often called, and thence on to the shoe city of Lynn. The route was followed on to Salem, known throughout the country as the "Witch City," and then to Prides Crossing. Here the beautiful lawns, shrubberies, and rockeries of the Mrs. Henry C. Frick estate were observed, as were also the attractive plantings of shrubs and trees, the delightful willow walk, and the lovely rose walk of the estate of Mrs. William H. Moore.

The party next toured to Orchidvale, the A. C. Burrage estate at Beverly Farms, where an inspection was made of the wonderful orchid collection, regarded as the finest private collection of orchids in this country. A buffet luncheon was here served. Leaving Orchidvale, the automobiles proceeded along the ocean route through Manchester, Magnolia, a popular resort, and Gloucester, a quaint and charming city, as well as the greatest fishing port in America, whose harbor is one of the most beautiful on the eastern coast, and on to Ipswich, where Castle Hill Farm, the estate of Mr. and Mrs. R. T. Crane, Jr. and over which Robert Cameron, the President of the Association, presides, is located. Mr. Crane was present to welcome the guests to his estate, speaking of the pride he felt in his estate and that it had never before been in the excellent condition it was to be found in today. Mr. Mackintosh responded on behalf of the guests, thanking Mr. and Mrs. Crane for their cordial hospitality. This estate commands a beautiful view of the sea, and has miles of rolling dunes of pure white sand, on which an old fashioned clambake was thoroughly enjoyed by the two hundred twenty guests. The maze, the rose garden, the Italian garden, and the broad stretches of lawn before the mansion were of particular interest.

Leaving Ipswich, the automobiles passed on to the Thomas E. Proctor estate at Topsfield, where James Marlborough, who is in charge, escorted the party through the extensive greenhouse range, in which were to be seen the finest Winter flowering begonias found in America, and other wonderful specimen stove plants. The convention party was treated to refreshments as the guests of Mr. Proctor, after which it was conducted through the unique and especially attractive rock garden.

The final stopping place of the first day's tour was at Cedar Acres, Wenham, where over sixty acres are planted in dahlias and gladioli, which, together with the charming floral display house, were visited. The guests partook of a delightful repast

before departing on the return trip to Boston. Mr. Kenneday on behalf of the visitors thanked Mr. and Mrs. Tracy for their cordial welcome to which both Mr. and Mrs. Tracy responded.

On the following day the convention party motored to Cambridge, passing around the buildings and campus of Harvard University, which is the oldest college in this country, and stopping at the Botanic Museum where the famous Ware collection of glass flowers is housed. These glass flowers, prepared by Leopold and Rudolph Blaschka, are so perfectly modeled that it is difficult to distinguish them from real flowers.

The automobiles proceeded on to Lexington, famous for the part it played in the early history of America, and on to Concord, where the party stopped to view the statue of the "Minute Man," which marks the spot where the farmers arrayed themselves against the British. Concord is also the home of noted American authors, Hawthorne, Emerson, Thoreau, and Alcott, whose houses are still standing. Passing through Sudbury, where still stands the ancient Wayside Inn, erected in 1687, the automobiles continued on to Wellesley, driving by the buildings and campus of Wellesley College, and on to the Henry S. Hunnewell estate, where the attendants to the convention became the guests of Mr. and Mrs. Hunnewell. Mrs. Hunnewell received the ladies in her home where luncheon was served to them on a broad piazza, overlooking one of the finest scenes of hills and water to be found anywhere. Mr. Hunnewell was host to the men of the party at luncheon which was spread on the lawn. Following the luncheon, Mr. Mackintosh thanked Mr. and Mrs. Hunnewell for the hearty reception they had extended, which they graciously acknowledged.

The automobiles drove through the Arnold Arboretum, one of the most notable arboreta in the world, covering two hundred seventy acres. Practically every tree and shrub in the world which is able to thrive in the New England climate is to be found in these grounds, which although an adjunct of Harvard University also belongs to the park system of Boston, the college and city sharing in its support.

At Brookline, the next stopping point, the estate of Larz Anderson was visited, which contains among other ornamental features, an Italian and a Japanese garden. Here the party was treated to a delicious spread. A visit was made to the estate of Mrs. C. G. Weld where there are long stretches of beautiful lawn; to Faulkner Farm, the E. D. Brandegee estate, among whose features are an Italian and an interesting rockgarden, and to Prof. C. S. Sargent's estate, Holm Lea, noted for its sweep of lawns, lilacs, rhododendrons and rare trees.

As the photographs of the convention and the detailed description of the estates visited were received too late for publication in the September number, they will appear in the October number.

LADIES' ENTERTAINMENT

From the very hour the ladies attending the convention arrived at the hotel, until the moment of their departure, they were royally entertained. The Ladies' Committee, including Mrs. B. Hammond Tracy, Chairman; Mrs. W. N. Craig, Mrs. Wm. Anderson, Mrs. George F. Stewart, Mrs. Duncan Finlayson, Mrs. Andrew Rogers, cordially greeted the ladies on their arrival and most courteously treated them throughout their entire stay in Boston. Following the very interesting opening meeting on the afternoon of the first day of the convention, a reception was held at Horticultural Hall at which the Ladies' Committee served tea. In the evening while the men enjoyed a most instructive illustrated lecture on the Arnold Arboretum delivered by E. I. Farrington, at Horticultural Hall, a theatre party was formed for the ladies.

On the morning of the second day, the ladies in attendance at the convention separated into groups to visit the shopping district

of Boston, returning to Hotel Brunswick at noon to become the guests of the Ladies' Committee at luncheon. The afternoon hours were passed at the fashion show staged at the Copley Plaza by Filene. The ladies graced the tables at the annual banquet and were among the guests entertained on the two days' trips to notable country estates in the vicinity of Boston and along the North Shore.

PRESIDENT'S CAMERON ADDRESS

(Continued from page 264)

dening creates a love for horticulture and in this way the beautifying of home surroundings and the improvement of villages and towns are feeling the effects of this good work. The exhibitions of the products of children's gardens are larger and of better quality than ever before. Let us help this good cause along by giving information and encouragement to those who need it.

The building up of the Association with new members is—as it is in all organizations—an important factor. The growth of our organization is slower than it might be because we are more careful in selecting members so that they may be of the standard required of the profession. Our endeavor should be at all times to conduct the affairs of the Association with such uprightness that no criticism should be heard from members or others. I don't mean by this that our Association can be made perfect. I should rather see a limited number of interested members than a large increase in membership from sources that would not be interested in the welfare of the organization.

The time of the year when we hold our convention should be given consideration. We hold the convention too late in the season and the estates which we visit are not seen at their best. This part of the program is of great educational value to gardeners. I personally believe that about the middle of August would be nearer the right time to see gardens and estates when they would be at their best. This subject should be given our consideration.

Let me ask every member to do his little bit to help the organization along. Our profession is the oldest and we may be proud of it.

I regret that our Secretary, Mr. Ebel, was indisposed and had to be absent from the office in New York for several months. I am pleased to see him here today. I wish at this time to thank, most heartily, Miss Dorothy Ebel for the excellent service she gave in her father's absence. She conducted the secretarial work most satisfactorily.

I wish to extend my warmest thanks to the ladies and gentlemen on the various committees who have worked so hard to make this convention a success. I wish also at this time to especially thank Mr. William N. Craig for the interest and hard work that he has put into all the details of the convention.

WESTERN PENNSYLVANIA BRANCH

A meeting of the members of the National Association of Gardeners of this district was called by Manus Curran, President of the Sewickley Hort. Society, on Saturday, Sept. 2, 1922, to consider the advisability of forming a district branch of the N. A. G. Mr. Curran was appointed temporary chairman and Henry Goodband, temporary secretary.

It was decided to call this branch "The Western Pennsylvania" branch of the N. A. G. John Barnet was appointed a delegate to the Boston convention held on Sept. 12 to 15.

The following members were heartily in favor of forming this branch: Manus Curran, John Barnet, Wm. Thomson, Jr., Frank B. Reig, John Carman, Arthur Bonsey, Herman Rapp, Wm. Jess, Wm. Falconer, Niel McCallum, David Fraser, Louis Barnet, Alex. Davidson, R. W. Ross, Henry Goodband.

HENRY GOODBAND, Secy. pro tem.

The Most Greenhouse For the Least Money

That Is Practical

BY the least money, we mean, the least that is con-
 sistent with lastingness and the making of a happy,
 healthy home for your plants.

It is a house we have been building for years.

A clean cut, thoroughly practical greenhouse, in which
 the ornamental touches and extra refinements, so to
 speak, have been eliminated.

Still, it is decidedly good looking, and will grow just as
 many and just as fine quality of flowers as any house that
 costs more.

The times have made so many folks want to strip things
 for the running, as it were, that they quickly buy this
 Practical Purpose house, when they would not our
 regular one with its curved eave and other features.

Thinking you might feel something the same way, here
 it is. Glad to send you fullest of particulars, or one of
 us will come and talk it over with you.

AMONG THE GARDENERS

James Methven succeeds W. N. Craig as superintendent of Faulkner Farm, Brookline, Mass.
 Irving Stewart, son of George F. Stewart of Waltham, and formerly head gardener at the Portland parks, Portland, Me., is successor to James Methven in charge of the Cooley estate, Readville, Mass.
 Gustaf E. Karlson accepted the position as head gardener to H. A. Hayward, Franklin, Mass. He was formerly with Mrs. Adele D. Thayer of Franklin.
 J. H. Snyder, formerly in charge of the late General C. H. Taylor's estate, Buzzard's Bay, Mass., has secured the position of superintendent to Colonel E. H. R. Green, Dartmouth, Mass.

Alfred H. Wingett, 54, recently died at his home on the Allen Winden estate, Lenox, Mass., of which he was superintendent. He was born and educated in England and learned the profession of horticulture and landscape gardening in that country. Coming to America in his early youth, he immediately went to Lenox where he later secured the position of superintendent which he has held ever since. He was an expert in his line of work and well known in the profession of gardening, holding office in the Lenox Horticultural Society. He is survived by his widow, and daughter, Mrs. Charles M. Sears of Salem, by his first wife.

Albert Millard resigned his position as superintendent of Greystone, Mr. Samuel Untermyer's estate, at Yonkers, N. Y., and has been succeeded by Charles A. Mackay, who recently arrived from England.

LOCAL SOCIETIES

WESTCHESTER AND FAIRFIELD HORT. SOCIETY.

The regular monthly meeting of the above society was held in the Y. M. C. A. building, Greenwich, Conn., on Tuesday, August 8.

An Exceptional Chance To Secure Fine Fruiting Canes of Pot Grown Grapes

They are an exceptionally choice lot. When we say they are choice, they are exactly that.

Every one is a three-year-old fruiting cane, 7 feet to 9 feet long, and in 8-inch pots.

They are just right for grapery border planting. Or for growing on in pots.

They are large enough to carry several bunches, depending, of course, on the size bunch you want.

For table decorations, these canes are the ideal size.

Varieties

- Gros Colman**—Black grape, for late season.
- Foster's Seedling**—A white seedling of Buckland Sweetwater; good setter and hangs well.
- Black Alicante**—Massive bunches, excellent color and bloom.
- Black Hamburg**—Delicious grape, best for ordinary purposes.
- Muscat of Alexander**—Pale amber of exceptional merit, most suitable for growing on in pots.

Price

\$7.50 each in 8-inch pots; \$70 per 10. Quantity limited, so get your order in at once.

The special exhibition committees reported great progress in arrangements for the annual Dahlia Show, which is to be held in the Y. M. C. A. building, Greenwich, September 19 to 21.

One new member was elected, and the usual display of flowers and vegetables was well filled. First prize was awarded to Wm. Smith for a collection of dahlias; second, to John Andrews, *Primulinus* hybrids; third, W. D. Robertson, fancy leaved caladium. Other exhibits were as follows: James Linane, *Lilium speciosum*; H. F. Bulpitt, *gladiolus*, *Primulinus* hybrids; James Tough, *Buddleia variabilis*; Wm. Smith, *gladiolus*. James Linane received first prize for collection of vegetables, and H. F. Bulpitt, second, for tomatoes (Best of All).

P. W. Popp gave an interesting talk on his trip through the West, describing the weather and horticultural conditions prevailing there. T. J. BULPITT, Cor. Secy.

CLEVELAND HORT. SOCIETY.

The regular meeting was held on August 10, with R. P. Brydon in the chair.

The exhibits of the evening were two vases of *gladioli* by F. Eckhardt, who was awarded a Cultural Certificate for them.

Two new members were elected and two more proposed for membership. The chrysanthemum show schedule and prize list was presented and approved by members. The show will be held in Woodward Masonic Temple, Nov. 9 and 10.

Thursday, Aug. 16, a number of gardeners from Sewickley, Pa., visited Cleveland as guests of this society, there being about twenty-five in all. After visiting a number of places, a dinner and supper was served, and about forty-six were present. Mr. Wether, made the operative speech, welcoming the visitors in behalf of the society, and Mr. Barnett, of Sewickley, Pa., returned thanks in behalf of the visitors, in which he mentioned the Cleveland members who had been present at the Dahlia Show in September. Mr. Manning, of Boston, was called on for a few remarks and Mr. Popp and J. C. Manning, of Sewickley, spoke on the beautiful estates that had been visited and of the pres-

How to Tell Exactly How It Will Look On Your Grounds

Send us a photograph of the location you have in mind, and we will transplant the greenhouses on it, just as we did in this particular instance.

You don't have to imagine a thing.

There it will be exactly as it would be.

We can take care of the complete building operation for you, relieving you of every botherment.

To our booklet, called "Owning Your Own Greenhouse," you are most welcome.

tates and of the enthusiasm it puts into their work.

O. M. Eastman, supervisor of the school garden department of Cleveland, talked on the development of that work in schools, and the help given by the local gardeners.

The party broke up by the visitors giving a rising vote of thanks and three rousing cheers to their hosts. W. J. Bruce, Secy.

THE OFFICIAL ORGAN

During the convention of the National Association of Gardeners at Boston, inquiries were made as to how the GARDENERS' CHRONICLE, as the official organ of the gardeners, can be improved to make it more interesting to them. It was the opinion of most of those approached that by supplying more news of the doings of the gardeners; also what transpires at the local meetings of gardeners' societies which would be of interest to similar societies elsewhere; unusual experience in the garden which gardeners encounter in the cultivation of plants, would all add much to make the paper interesting to them.

The GARDENERS' CHRONICLE has often appealed to local societies and to gardeners individually to contribute such news as would be of interest to the gardening craft, but it has never met with sufficient response to be of importance. The editor will gladly give space to lively news items when they are received, but he is dependent on having them sent to him for the GARDENERS' CHRONICLE is not in a position to maintain editorial staffs throughout the field which it covers, which is national.

Will the gardeners reading this notice please direct the attention of their fellow gardeners and also of the meetings of the local societies to it?

EDUCATING WILD PLANTS

Those who attempt to introduce wild plants into their gardens by means of seeds, often find it difficult to get the plants established in this way. Although they seem to grow well enough in their native haunts, they are slow to germinate in cultivation or fail to come up at all. It is likely that we unconsciously contribute to this failure by treating the seeds differently than they are treated in Nature. For instance, we are likely to keep them in a dry room over Winter, when they are accustomed to lie in the cold and sodden ground through that season. It appears, however, that when wild flowers are introduced into cultivation and propagated by means of their seeds, the slowness to sprout wears off, and thereafter they grow readily. A scientific explanation of the facts seems to be that only those seeds which can grow at all in such situations are likely to leave descendants, and since children are like their parents, there is soon bred up from these a race of plants that is amenable to garden cultivation by the elimination of those less able to survive in such situations.—*American Botanist*

Aphine
*The Insecticide that
kills plant Lice
of many species*

SPRAYING

is as

Essential as Fertilizing

Successful cultivation demands a knowledge of the habits of plant insects and diseases, and the proper remedies for their control.

APHINE, an effective remedy against all sap sucking insects infesting flowers, fruits and vegetables, is free of the disagreeable odors and features of most insecticides. It invigorates plant life and is unexcelled as a wash for decorative plants. Aphine will not injure the most tender flower or foliage.

FUNGINE is an excellent remedy for mildew, rust, and other blights. It is readily soluble in water and contains no sediment. Fungine does not stain the foliage but cleanses it.

VERMINE is a soil sterilizer and vermicide. It destroys cut, wire, eel and grub worms, maggots, root lice and ants, and will protect your gardens and lawns from ravages under the soil.

There is but one convincing way for you to become familiar with the merits of these products and that is to try them out for yourself. It will prove worth while.

Sold by dealers in various sizes.

"Prolonged lives of trees for many years"

The tribute of Edward Parker to Davey Tree Surgery

on the Oliver Ames estate

The Davey Tree Expert Company,
Kent, Ohio.

Dear Sirs:

It is a pleasure to commend the Tree Surgery operations executed by your men on the Oliver Ames Estate over which I have charge. My careful observation has shown me that these men are most industrious workers, take a careful interest in their duties at all times, and certainly know their business as far as difficult surgery on valuable trees is concerned. Our many trees needed expert treatment and I feel that the work recently completed by your men will be of great material benefit and has prolonged the lives of some of them for many years to come.

Very truly yours,

Edward Parker, Supt., Oliver Ames Estate.

Every gardener and estate superintendent has a most important work in the saving of trees under his care.

Davey Tree Surgery brings to his aid the highest development of science plus a generation of experience. A careful examination of your trees will be made by appointment.

The Davey Tree Expert Co., Inc., 309 Elm St., Kent, Ohio.

BURPEE'S Winter Flowering Sweet Peas

For Your Greenhouse

THE BURPEE varieties of Early or Winter Flowering Sweet Peas are revelations of beauty. They have been the admiration of the many thousands of visitors to the International Flower Shows in New York and various other exhibits held by The National Sweet Pea Society and The Pennsylvania Horticultural Society.

Burpee's Sweet Peas have been Prize Winners everywhere. Our list includes the most exquisite shades in a complete range of colors.

BURPEE'S ANNUAL, the Leading American Seed Catalog, gives complete descriptions of all the beautiful Burpee varieties, and will be sent free upon request. Plant Burpee's Sweet Peas NOW for blooming in your greenhouse this winter!

W. ATLEE BURPEE CO.
Seed Growers PHILADELPHIA

TOTTY'S

THE Flower loving public is cordially invited to visit our new Flower store, at 4 East 53rd Street, off Fifth Avenue, and enjoy the exhibits of blooms of the world renowned Chrysanthemums from our greenhouses.

Here you will also find the new Rose of the century, "Hill's America," and other favorites among Roses and flowers of this season of the year.

Blooms are cut each morning at our greenhouses and sent direct to our New York store.

When visiting the Flower Show at Morristown, in October, drive over to our growing establishment at Madison, N. J., and inspect the growing plants.

We accept orders for plants now for later delivery, both at our store in New York and at our place in Madison.

HIGH QUALITY Bulbs • Seeds • Plants FOR AUTUMN PLANTING

This is the title of our Autumn Catalogue which we have been mailing to our patrons during the month of September.

If your name is not on our mailing list, write to us and we will send you a copy of this Catalogue at once.

For the past twenty-five years we have been supplying an increasing number of particular flower lovers with our Seeds, Bulbs and many of their garden needs.

HIGH QUALITY BULBS WHY WE USE THE EXPRESSION AND HOW WE ENDEAVOR TO MAINTAIN IT

High Quality Bulbs are bulbs of proper flowering age, grown in a careful manner; thoroughly ripened and cured; and selected for size. The bulbs listed in our Autumn Catalogue are grown in Bermuda, California, Japan, France, but principally in Holland. We contract with growers only for each variety listed. No grower in Holland, for example, grows all the varieties of Dutch bulbs offered by us. Therefore, we place advance contracts for the various varieties with specialists. The bulbs are carefully packed and shipped to us in the autumn.

On their arrival in New York they are immediately unpacked so as to avoid becoming "leated" and carefully arranged in our own building, examined and passed on by thoroughly trained men.

Things and Thoughts of the Garden

WILLIAM N. CRAIG

PLEROMA ELEGANS is an old greenhouse plant introduced about eighty years ago and native to the Organ Mountains in Brazil. There are many varieties of *Pleroma*, but for garden purposes *elegans* is the one most worthy of consideration. Years ago we were told that *Lasiandra* was the correct name and now botanists call it *Tibouchina*, but amongst professional gardeners the name *Pleroma* will continue to cling to it, just as they prefer to class *Codiaeums* as *Crotons*. *P. elegans* is sometimes grown into specimen plant size and being a lusty grower, a number of pinchings are needed to give it the necessary shape and size. Its deep violet colored flowers are of particular value in the garden during Summer and it is really one of our most persistent bloomers, the flowering season continuing for four or five months. In tubs it is seen at its best and if plants have been well pinched and tied in a little to make them shapely, they present a splendid show for a longer period than any other plant I can name. Propagation is easy and the plants being rapid growers, good sized specimens are soon attainable. While *Pleromas* will succeed in full sunshine, they are even better in partial shade.

* * *

Members of the National Association of Gardeners who were privileged to see the beautiful rose gardens on the estates of Mrs. R. T. Crane, Jr. at Castle Hill Farm, Ipswich, and Mrs. Henry Hunnewell of Wellesley were amazed at the wealth of bloom carried on the hybrid teas in the middle of September. It is commonly supposed that Massachusetts is too far north to permit of very successful out-door rose culture, and the picture of these two gardens with such a wealth of glorious flowers and foliage, free from black spot or mildew, caused many expressions of wonder. A very successful Newport, R. I., grower said the plants in his garden were almost leafless. Another from Pennsylvania remarked that nothing like that was possible near Philadelphia and a third hailing from favored Long Island, stated that his had few flowers, and foliage was badly mildewed.

These are not the only rose gardens in Massachusetts but they are good enough examples of what may be done in a rigorous climate, provided suitable locations are selected, beds well prepared and drained, plants frequently sprayed or dusted for insect pests and diseases, decaying foliage carefully removed as it falls (this is most important) and ample Winter protection afforded. This latter is a big and expensive item. Plants are all tied or laid down and buried with soil over which mouse proof wire

is placed and over this again, a Winter mulch. Ramblers, standards, and dwarfs are all buried in this way, the only absolutely sure method of Winter protection. No roses on their own roots are to be found in these New England rose gardens, as they are of little value, and the one time popular hybrid perpetuals are, sad to state, rarely met with.

* * *

In listening to an address by Ernest H. Wilson in Boston on his recently completed two years' world tour, I was specially interested in what he said of *Todea superba*, *T. hymenophylloides*, and *T. barbara* as found growing in New Zealand. Mr. Wilson came across many acres of them, especially the beautiful *T. superba*, growing in the forests in semi-darkness and where there was a constant drip. The ground where they luxuriated was marshy and to avoid sinking down, it was necessary to step from plant to plant of the *Todeas*. The plants were wonderfully luxuriant under these conditions and it seems not at all surprising that here and in Europe cultivators have trouble with these beautiful ferns in giving the necessary subdued light and constant sprays to make them feel in some measure at home.

* * *

Gladiolus primulinus, an African species, has given us the most graceful and decorative race of this popular bulbous flower. We ordinarily look upon gladioli as plants which grow for several months, flower, and then have a long period of rest. It came as a surprise therefore, to hear Mr. Wilson state that under the spray of the great Victoria Falls of the Zambesi River, *Gladiolus primulinus* was thriving most luxuriantly and evidently proving a perpetual bloomer. There no chance exists for any dry period as spray falls continually, in which *primulinus* was revelling. Perhaps in the southern tips of Florida and California where it is practically frostless, this useful gladiolus under irrigation might prove to be a perpetual bloomer as in its native home on the dark continent.

* * *

Amaryllis belladonna is the only true amaryllis, all of the many hybrids of varied colorings which are horticulturally called amaryllis and will no doubt continue to be so named are Hippeastrums. *A. belladonna* proves to be a useful hardy bulbous plant in many parts of America, but for many of us culture in pots or frames is necessary. The finest lot I have seen in New England is planted out in special frames where they can get the necessary Winter protection and also the equally neces-

sary Summer rest. The color of *A. belladonna* is so much more pleasing than that of the *Hippeastrums* that it is surprising that more are not grown. The flowers furthermore are produced in Autumn, a period when really nice blooms are none too abundant.

In Cape Colony Mr. Wilson found *A. belladonna* wild, in great abundance and a point he mentioned was that residents there informed him that the plants always bloomed far more profusely after a fire had swept over the land where they were growing. Whether this cleans out various plants likely to smother them in some measure, or whether the potash from the fire gives the plants a necessary plant food, I am not prepared to say, most probably the potash does the trick.

* * *

Nerines are most useful and beautiful Fall flowering bulbs, and they are rapidly growing in favor on private estates. Some wideawake commercial men are also taking up their culture. Thomas Roland, of Nahant, Mass., one of the most expert plantsmen in America, grows a large quantity and annually raises many thousands of seedlings. Charles Sander, superintendent to Prof. C. S. Sargent, of Brookline, has for many years been a large and successful cultivator and has flowered thousands of hybrids. H. J. Elwes in England is a great specialist with nerines and has raised many fine varieties. At one time *N. Fothergilli major* was about the only sort grown, it is still probably the best and most vigorous variety, but in addition to the scarlet forms, there is a wide range of colors, varying from deep rose, pink, salmon, and mauve to pure white. *Fothergilli* produces much the largest bulbs but the smaller bulbed varieties bloom more profusely and usually somewhat later. I have had as many as fifteen spikes on a six-inch pan of *N. excellens*.

* * *

Points to remember in the culture of nerines are, that while growing, they require a good water supply and some feeding, also a cold house. When growth is completed, plants should be gradually dried off and as leaves become discolored, cease watering entirely and during the resting period, they should be given a thorough baking in the sun, preferably under glass. Nerines furthermore will flower only sparsely until pot bound, and for that reason, they should be kept in the same pots for several years, until crowded bulbs make a shift necessary.

Owing to the long spell of warm dry weather in September and October, Autumn tints are this season unusually brilliant and the fruits on all berried trees and shrubs have an intensity of color which make them extremely attractive. Amongst the berried shrubs, the *Symplocos* are particularly striking on account of their bright blue berries. *S. paniculata*, also called *cratagoides* is the best known species and a native of the Himalayas. It is hardy as far north as New Hampshire and any one desiring to possess a striking berried plant of unusual color should procure one. As it is a robust grower, it should be given a location where it can have space to develop and show its individuality. While there are nearly three hundred species of *Symplocos*, only *paniculata* is hardy for our cold states. *S. tinctoria* requires a warmer clime and about all other species are tropical or semi-tropical.

* * *

Fall fruiting strawberries and raspberries make a welcome addition to our desserts. The everbearing strawberries have become quite popular and in October they are bearing abundantly fruits of excellent flavor. Lucky Boy one of the newer varieties is the best I have yet come across. Among raspberries, La France now carries quantities of fine fruit and the flavor is very good. This is the finest acquisition among raspberries for many years. It is not quite as hardy as Cuthbert, St. Regis and other better known varieties, but given a little Winter covering, it comes through in good shape. Raspberries and cream in mid-October are very welcome, even though there is at that time an abundance of other fruits.

* * *

Poultry yards are not usually associated with flower culture. I was therefore very much interested and pleased to note how a thrifty and neat Swedish family screened, shaded, and at the same time, adorned their yards. From a distance no wire fences were discernible, outside of them such plants as *Boltonias*, *asteroids*, and *Latisquama*; *Helianthus* "Miss Mellish" and *Helenium autumnale superbum* were planted. As these grew up, a stout string was run around them and at intervals fastened to the fence to hold them erect and the effect was certainly very good. All these plants are of simple culture and as the bulk of private estates now have poultry yards, here is a way to screen them and also beautify them. *Clematis paniculata* I have seen used on one occasion for a similar screening purpose.

Flowering Plant Novelties

FRANK B. MEYER

THE objects of this little essay are two. The first is to point out a way in which amateurs may, even with but comparatively small means, have enjoyment of the rarest novelties among the flowering plants of special favor in their eyes and even have possession of treasures too costly for their individual purses. The second object is to try to maintain the thesis that by professional gardeners and their employers the rare and the most beautiful among several flowering plants of great recent improvement are appreciated too little.

The first object may perhaps be attained sufficiently by telling of a plan naturally evolved by five lovers of flowers in a small town of the Central West. In that town a dentist used to find fresh air and relief from a profession that, more than most people think, wrecks the nerves of

the practitioner as well as those of his patient, in his garden. A visiting friend, a lawyer who had risen to the dignity of a judgeship, was attracted by a bed of flaming oriental poppies, and soon was himself also sowing seeds and setting plants. The persuasion to go and do likewise came to a neighboring manufacturer in the form of an armful of beautiful gladiolus blooms presented at the "psychological moment." In the time of the loved wife's illness a second lawyer and judge was brought to realize what flowers can say when the sympathetic dentist brought to the door an armful of big peony blooms. A retired business man, whose modest competency was acquired without his having accumulated much to retire to, was interested by the evangelizing friend, one opportune day in

(Continued on page 286)

The Regal Peony

FLORUM AMATOR

THE peony by reason of its stately beauty occupies a commanding position in our flower gardens from early May till mid-June. It is indeed a regal flower today just as it was nearly fifteen hundred years ago in China where it had become the chosen flower of emperors and the admiration of painters and poets, who made it a subject for brush and verse. The peony is an enduring plant; it not only has maintained its place as a favorite through the centuries but also is the hardiest of all our herbaceous perennial flowering plants.

In general cultivation we find only three species of the peony. These are *Paeonia officinalis*, which grows wild in southern Europe and which received its name, *Paeonia*, now given to the entire genus, from one Paeon, a physician who according to myth or tradition, healed the wounds of the war god, Mars, with the roots of this plant; *Paeonia moutan*, the tree peony; *Paeonia albiflora*, or as it is more generally called, the Chinese peony. Both the Chinese and the tree peony are indigenous through northern Siberia to the borderland of China.

There are comparatively few varieties of *Paeonia officinalis* although in mythical history it antedates both *P. moutan* and *P. albiflora*. The most cultivated of the *P. officinalis* varieties is *rubrum*, the well-known red peony of the old time flower gardens, grown chiefly today because it flowers from two to three weeks earlier than any of the *P. albiflora* varieties to which it is much inferior, but, nevertheless from its early blooming habit, worthy of cultivation.

P. moutan, the tree peony, receives its common name, tree, because it grows in a shrub-like form and attains a height sometimes of three to four feet. Its large blooms are in extremely delicate shades of color and also appear three to four weeks earlier than those of *P. albiflora*. The plant of *P. moutan* is entirely hardy, but the buds, on account of appearing very early in Spring, unless protected, are often injured by late frosts. The tree peony though it has not gained in America or Europe the popularity of *P. albiflora* (the Chinese) varieties are fully worthy of cultivation. This peony was brought through the efforts of Sir Joseph Banks into England in 1794. An envoy of the Dutch East India Company after his travels through China in 1656 had enthusiastically described this peony in a report to his company, which report Sir Joseph Banks had read.

P. albiflora, which in its extremely large and constantly increasing number of varieties, is the most widely cultivated and most popular of all the species, was brought into England not long after the tree peony. The precise date is not fixed but Sir Joseph brought into England *P. albiflora*, variety *fragrans* in 1905, and *P. albiflora Whittleyi* was brought in by Mr. Whittley in 1808.

Thus the peony, the favorite flower of the Chinese emperors as early as the fifteenth century, and received with great favor in Japan in the seventeenth, was not brought into England till about the eighteenth century. From England the peony was soon introduced into France and about the same time into America.

In France, however, in the gardens of the nobility under the skillful cultivation of the French gardeners, the modern history of the peony began, and many sports appeared and hybrids were produced. The French especially, and also the Dutch and Belgian peony specialists, have given to the world many new and beautiful varieties of the *al-*

biflora species. M. Dessert and M Lemoine of France during the last two decades have disseminated many of the finest varieties and in England the Kelways have added desirable varieties to the list. It was not till about 1850 that peonies began to be popular in America, though Mr. McMahon in 1806 speaks of five kinds, and William R. Prince mentions a collection of forty varieties in 1828, and again in 1862 speaks of having twenty varieties of tree peonies in his garden at Flushing, Long Island. In the West, H. A. Terry and Mrs. Sarah A. Pleas of Iowa, and in the East, John Richardson and George Hollis have sent out not a few varieties of merit.

The claims of the peony for a large place in our gardens are the glorious beauty of its large flowers in many colors and forms; hardiness even where the Winters are severe, and hence permanency; easy culture; ready adaptability to different soils and situations; freedom from disease and insects; utility as cut flower and as a plant in artistic landscape effects.

The species of *Paeonia* known as *albiflora*, or Chinese peony, has been divided into eight types, based on the forms of the flowers, by the American Peony Society: single, having a single row of white guards and yellow pollen bearing stamens; semi-double, having several rows of wide petals, a center of stems and partially transformed petaloids; Japanese, with wide guards the same as single, but with stamens and anthers greatly enlarged into narrow, thick petaloids of various colors, tipped with vestiges of the yellow anthers devoid of pollen; anemone, going a step further in the process of doubling, and having the stamens all transformed into short, narrow petals forming a round cushion in the center of the flower; crown, having wide petals developed in the center of the flower, forming a high crown with narrow, short petals in a ring or collar around it, the crown and guards often being of one color, and the collar another or lighter shade; bomb, in which all the center petals are uniformly wide, approaching the guards but distinctly differentiated from them, and forming a globe-shaped center without collar or crown; semi-rose with petals all uniformly wide but loosely built and with a few pollen bearing stamens visible or nearly concealed; rose in which the process of doubling is completed, all the stamens being transformed fully into wide evenly arranged petaloids; similar to guards, forming a perfect rose-shaped bloom.

As J. L. Coit of Cornell University has said in his excellent monograph on the peony: "The peony will grow almost anywhere in the United States where apples will grow." Peonies will thrive to some measure in almost every location, where the drainage is good, but will not endure wet feet. They prefer a moderately moist, deep, rich sandy loam. In such location and soil we may plant peonies without further preparations.

Though the location and soil are both favorable, better results may be obtained, if several months or weeks before planting we incorporate in the soil to the depth of two feet a layer, of six inches or more deep, of thoroughly decayed manure. If where the peonies must be set out, the soil is naturally very poor, it should be removed to the depth of two feet and after a layer of manure is dug into the bottom of the excavation, it should be filled up with a compost of about three parts of rotted sod or rich field sod, one part rotted manure and one of leaf mold. If the field soil or sod is heavy clay, incorporate about one sixth part sand. When finished, the surface of the bed

or border should be about six inches above the level to allow for settling.

In setting out peonies, a space three feet in diameter should be allowed for each plant. The crown of the plant or roots, when set out should be no more than three inches nor less than two below the surface. Too deep planting sometimes appears to cause a paucity of flowers. The roots, after they are planted should be covered with several inches of coarse, strawy manure, or manure and leaves, the coarser part of which should be removed in the Spring and the finer dug into the soil, care being taken while so doing not to injure the tender crowns. Preferably peonies should be set out in September or October. From these autumn-set plants, some blooms may be expected the next May and June. Peonies may also be planted in early Spring, but these Spring-set plants should not be expected to flower to any extent until May and June of the next year.

Peonies have a variety of uses in the garden and landscape work. They are suitable for border planting, especially when the border is at the same time the boundary of a garden or lawn. They are even more effective when set at intervals among other herbaceous perennials than in a continuous row. Clumps of peonies may be set on small lawns or on each side of steps leading up to a veranda. They are equally as effective when planted in great masses at the turns of drives or walks. Large groups of peonies of the same variety or of varieties whose flowers harmonize in colors, may be planted in open spaces on large grounds, giving an excellent effect. Peonies are not averse to a partly shaded position and in such, their blooms are of a deeper color and their flowering period is lengthened.

The peony is a plant which in poor soil and in an unfavorable location, and with little care, gives greater satisfaction than almost any other plant under like conditions. Nevertheless, it greatly appreciates a suitable location, rich soil, and careful culture, and freely responds to these better conditions by producing blooms of a higher quality and in larger number.

FLOWERING PLANT NOVELTIES

(Continued from page 284)

the Spring, during a long ramble in the woods, for wild flowers had not been altogether neglected in favor of those modified, and possibly not in every case improved, by the hand of man.

With interest thus aroused the five friends were stimulated by visits to one another's gardens. Each took delight in showing to the others his latest acquisitions. The beholding of a new prize in a garden visited awakened the desire to possess it, or something like it that might be better. But such rivalry began to be expensive and sometimes the same gladiolus, iris or peony, tulip or narcissus, was found in two of the gardens, which were not far apart. Hence came the idea: Why not have an understanding in accordance with which the expensive novelty might be enjoyed by all five friends while it would be a drain upon the treasury of one alone? This was then crystalized, without writing or even oral pledges, into a definite plan that led to conferences and agreements. The one by-law was that when the game might tend to make the members of this unique organization evasive, deceptive or less manly, they would quit. There was found need of such determination, to be insisted upon with firm will, for the plan naturally led, as plans and bulbs increased and became capable of division, to exchange.

But now, after several years of trial, the association of the friends continues and continues with great success. In the case of the *Gladiolus*, for example, the development

of which into splendid new varieties has been swift and very marked, there is scarcely a single variety of note, no matter where or by whom it was originated, that is not found in one of the four gardens, for one of the five friends has passed away. Even the man who is perhaps most famous of all in the world of this flower comes several times each year to study the collections of these amateurs.

In view of the fact that so much enjoyment and cultural value is found in the study and cultivation of improved floral novelties by amateurs the question might well be raised: "Why is it that these treasures are so little known and appreciated, with some gratifying exceptions, by professional gardeners and their employers?" Is the answer that gardening on a large scale, even that planned by landscape architects and professional designers, is too stereotyped? They seem nearly all to think that the old and the tried are the best and that to enter into the new fields opening up would involve perplexity and confusion. And it is true that the varieties offered in the catalogs of specialists are multitudinous and that some of the old varieties are still among the best. *Iris Pallida dalmatica*, Peony *Festiva maxima*, and *Gladiolus America* are hardly surpassed, all points considered. But there are new irises, new peonies and new gladioli that ought, if possible, to be in every garden and which are worth searching out. When found they will yield satisfaction corresponding to that afforded by new roses, carnations, chrysanthemums and orchids. The desirable new among the four flowers named last are more quickly taken up by the professionals, largely because they are grown in glass houses and consequently can be made to yield quicker results and can be seen more continuously. They are propagated more easily and are, as a rule, seen more conveniently at shows. But the outdoor plants, like the peony and the iris, require planning in the garden and preparation of soil at a season when the general work upon a big place is pressing. And this work still demands much attention when the flowers can be seen at competitive shows or in the exhibition grounds and growing fields of specialists. That such visits, even at the sacrifice of some other things, would be worth while would soon be evident in a quickening and deepening of interest in finer gardening. Employers should not only see to it that their superintendents and gardeners have such opportunities; they ought themselves to enter into the enjoyment of the finest embellishments of modern gardens.

The undertaking on the part of gardeners and owners is not formidable, nor does it any longer involve one in perplexity and confusion. The national organizations like the American Peony Society, the American Iris Society, and the American Gladiolus Society publish from time to time reliable estimates of the desirability of all varieties of the flower that is of their especial interest. The specialists growers themselves now give, as a rule unbiased advice in selecting, and many of them frankly give the authoritative ratings. Increasing attention on the part of professional gardeners and their employers would win favor for the organ of the National Association of Gardeners, our own GARDENERS' CHRONICLE, from the advertising specialists, growers who know, as the writer knows from talking with a number of them, have great cause to lament that the very persons who ought to enjoy most their finest products are giving little encouragement.

The best things are nearest,—light in your eyes, flowers at your feet, duties at your hand, the path of God just before you. Then do not grasp at the stars, but do life's plain, common work as it comes, certain that daily duties and daily bread are the sweetest things of life.

—SELECTED.

Water Gardening

ARTHUR SMITH

IT is not only from the mountains, the prairies, sunny fields, or shady woods, that our garden flora come. Rivers, brooklets, margins of lakes, are all invariably fringed with lovely flowers, and fleets of water lilies sail in the deeper waters.

The artistic possibilities of any home surroundings are doubled by the introduction of a fair amount of water. Water always furnishes a pleasing addition to a landscape, and although every country place cannot be so situated as to be blessed with a stream or lake as part of its attractions, yet where they are absent there is sometimes much which could be done in the way of artificially producing a situation in which the many beautiful hardy aquatic and sub-aquatic plants will thrive.

Where streams, ponds and swampy places exist upon an estate there is no part of it which can more easily be made naturally beautiful. While Nature always does much in this direction, situations are frequently seen which are in an unpleasant and unhealthy condition, when there is no reason why they should not be places of beauty, instead of an eyesore. Besides the great variety of picturesque effects that are possible with water, it affords the only means of growing the many worth while plants which are only happy in, or close to water, the chief feature in some being flowers and in others foliage.

Streams with a swift current running between steep banks do not lend themselves to water gardening, but in these cases use can generally be made of the water to supply an artificial pool or lakelet. There is no more attractive addition to any garden than a quiet pool with suitable plants growing both in it and around its margins. There is a soothing effect in the appearance of such a pool on a hot sunny day which is fascinating, and which defies comparison with any other part of the home. It is therefore worth while going to some trouble and expense to secure a feature of this kind, and it is also one of the many things connected with *hardy* plant gardening in which the first cost is practically the only one of any moment.

Of course, the most beautiful of all water gardens are those having their foundation in a pellucid, slow running river, as their natural features are so much better than anything we can make artificially, and the existing vegetation is also always natural to the situation. With a little thought much of this can be so blended with introduced plants of greater range, and in other ways which will suggest themselves to those of artistic taste, that a place of increased beauty may be created through the refinement of Nature by art.

When constructing an artificial piece of water, the available water supply has first to be considered, as without a *regular* supply it is useless to attempt a water garden. Therefore, a water garden should be made proportionate to a certain available supply of water. It is surprising what can be done with a small quantity, provided only that it never fails. A continuous rush of water into and through a pool is not only unnecessary but positively harmful to the welfare of the plants, the more so if the water has been pumped from a well or comes from a public water supply, as in these cases it is invariably cold and hard.

In this connection I am reminded of a pool, really a cement tank, existing in the center of a sunken garden. The tank has to be drained in the Winter, therefore the water lilies are in tubs so that they can be taken in and kept out of the reach of frost. A fountain plays in

the center of the tank and there is also another flow of water into it, both of these are cold and hard. That a continual flow of water of this description into the tank has a very adverse effect upon the plants is very apparent, as their foliage is small and soon dies, and the floral effects amount to very little; and so far as beauty is concerned, it is conspicuous by its absence. To succeed with water lilies in a tank of this kind all that is required is a sufficient inflow of water to scarcely more than cover loss by evaporation, in which case the water will always be during the growing season more or less warm, so that the plants will thrive instead of struggling for existence.

Fortunate indeed are those through whose grounds runs a perennial stream, even if it is only a very little one, for with the help of this, quiet pools can easily be constructed to any extent the conditions will permit. If it is not possible to use the stream itself as part of the water garden, sometimes the water from it can be diverted or conveyed by underground pipes to a suitable site for such a garden. In any case select as low-lying a place as possible, a natural depression if one can be found, where one can stand above the water and look down upon the plants. Water so placed that there are lower parts of the garden all around it looks incongruous and out of place. Unless one is making a pool or tank in a sunken, or an enclosed formal garden where it should be rectangular to conform to the other lines of the spot, every care should be made to prevent any artificiality in the appearance of the outline. Regular curves of circles and ovals are utterly out of place and look ridiculous in a landscape with irregular and natural features. In order to be effective, the outline of a piece of water must not only be irregular, but it must also be in accordance with the laws of Nature, and, as in most cases, the natural pond or lake is merely an expanded stream or river, we must look to the shore lines of the latter for guidance in the formation of artificial ponds.

In a natural stream the curves are mostly due to the water meeting with some obstacle which causes a deviation in its course. We find invariably that where a promontory, a projecting rock, or some other interference causes an alteration in the course of the water, the latter is thrown against the opposite side with greater force, and unless the ground is very hard a portion of it is washed by the impact and an extended recess is the natural result.

In the same way artificially constructed pieces of water to look natural should have the largest and the boldest recesses opposite, or nearly opposite, the largest promontory on the other side. The shore line should not terminate abruptly but should form a slope continuing below the water level.

Even when a constant stream flows through an estate the opportunity for water gardening is not always made the best, or any use of. One of the worst cases that has come under my observation was upon an estate where the grounds sloped down to a meandering stream which had naturally widened itself out to a limited extent into bays and still pools, altogether ideal conditions for water gardening were presented. But the treatment of it consisted in building a wall all along the margins; making a snake-like gravel walk along the stream about ten feet away from it; at intervals on both sides of this walk, round- and oval-shaped beds were cut in the lawn, filled every Summer with bedding plants. So far as the water

itself was concerned a good collection of water lilies had been brought together, which having seen, the first desire of any one with a modicum of good taste would be to get away from it as quickly as possible.

Outside the boundaries of this estate along the same stream, Nature had provided a splendid object lesson on the principles of how to water garden. The native species of water lilies are there, and the margins are delightfully covered with a multitude of worth-while plants, with a complement of small trees and shrubs. Altogether this water garden of Nature's is a spot where one can spend hours, leave with regret and the hope to again have the opportunity of revisiting it.

It is, of course, obvious that we can increase the natural opportunities which a stream gives us. If there are no bays of still water, these can generally be formed with little trouble. Sometimes the height of the banks and the contours are such that nothing more is required but a small dam to raise the height of the water a couple of feet or so.

The general treatment of the surroundings of water depend somewhat upon the conditions which exist. The margin should be laid out to conform to natural surroundings, and if the environment is not harmonious it should be made so. An occasional tree or two and some shrubs to break the sky-line, and to throw reflections of light and shade into the water, are advisable.

Water margins can be developed in numberless ways, weaving all sorts of plants suitable to wet and moist conditions into multitudes of variations.

In planting the shore of a piece of water, it is the ground which projects into the water which should be furnished with the largest and boldest growing plants. This is not only perfectly natural, but it also has the effect of partially concealing the bays. Water thus treated will appear larger than it really is, and a walk along the shore will reveal surprises at almost every step.

Regarding plants suitable for a water garden, it must be remembered that mainly three distinct conditions exist: we have deep water, shallow water, and the moist earth at the margins just above the water level. Unfortunately when water is bounded by masonry only plants which will grow actually in the water can be used and therefore three-fourths of water garden possibilities cannot be obtained.

It is very important to realize one's limitations when planting, especially the water itself. A piece of water covered entirely with vegetation has entirely lost its charm and is little better than a swamp.

A water garden must always have pieces of clear, open water, and one must regulate both the quantity and the species of the plants used so as to secure this end. A stretch of clear, still water always greatly increases the restful and quieting influences of rural scenery. Of course there is not room for much open water in a small artificial pool, but however small this may be there should always be a portion of it not covered by plants.

For deep water, water lilies of course take the first place. The depth of water, absolutely necessary for the growth of these subjects is not great, but consideration must be given to the depth to which water freezes. These plants are found growing naturally in as much as six or eight feet of water, and it is always best to have a few inches of unfrozen water above their roots in Winter.

The best time to plant water lilies is just before they start into growth, or about the second week of May in the latitude of New York, although success is not impossible if planted any time from April until September. Whatever the conditions as regards mud at the bottom of the water, it is well to prepare a compost made up of equal

parts of good fibrous loam and old cow manure. Wickèr baskets, or boxes with plenty of holes in them not less than two inches in diameter, holding about half a bushel, should be half filled with the compost; put in the lilies spreading their roots out properly, nearly fill up with compost, adding half an inch of coarse sand to the surface and a few stones weighing two or three pounds each, and then sink into the water at the required spot. Water lilies should be planted from six to ten feet apart according to their habit of growth.

No praise given to water lilies has approached exaggeration even when confined to our native species, but the newer hybrids raised by Tricker in America and by Marliac in France, have greatly added to their characteristics, not the least valuable of which is the longer season of flowers which the hybrids give. In making a selection regard must be given to the extent of water to be planted; where the area is large enough to be capable of supporting plants by the hundreds the question presents no difficulties as they are all worth growing.

America has been highly favored in the matter of water lilies, it being the only country which has native white, pink, and yellow flowered kinds; and taking the country as a whole it is the only one which can have so rich and so continuous display from April until October in the open water without artificial heat.

It may be mentioned in passing that sometimes a method is arranged in connection with growing the more tender and night blooming species in artificial pools or tanks, of having warm water run in so that the temperature of the water in which the plants are growing never falls below the necessary degree of seventy.

The common term water lily is given to three distinct genera, *Nuphar*, *Nymphaea* and *Nelumbium*, nearly all the native species being classed under *Nuphar*. Among the latter *advena* is the strongest growing and should only be planted in good sized pieces of water and not nearer than twenty feet to any other species. There are some half a dozen other native species hardy north of New York. Among the *Nymphaea*, *odorata* is the best known and with its variety *rosea*, Cape Cod Water Lily, are among the hardiest. This species has been one of the parents of many of the hardy hybrids.

The *Nelumbiums* are stately plants, and are easily distinguished by having both their flowers and foliage growing at a considerable height out of the water and not on the surface. These plants when once established in congenial situations spread very rapidly, and for this reason should not be planted near anything else, or even at all in a small piece of water unless one desires it to be confined to these alone. It is well to give them a bay to themselves when possible.

The common name for *Nelumbium* is *lotus* and there are only two species in the world—unless there are undiscovered ones—the native *N. lutea* and the oriental *N. nucifera* of which there are several natural varieties. The latter has wrongly been called the Egyptian lotus, but *Nelumbium* is not native of Egypt, although it was cultivated there in Roman times, probably for food, as they are now in Japan. The Egyptian lotus is a *Nymphaea*. While the oriental species is perfectly hardy provided it always has unfrozen water above its roots, the native species should be included in a collection provided there is room, as it is the only yellow *Nelumbium* in the world. *Nelumbiums* should only be planted in Spring, and that after the tubers have shown signs of growth.

Those who have not seen the *Calla*, *Richardia ethiopica*, growing wild in its South African home may be unaware that it is an aquatic, and can be treated as a hardy water

An Arnold Arboretum Plantsman's World Tour

WM. N. CRAIG

TWENTY-SEVEN months seems a long time to be away from home, but when over 100,000 miles are covered during that period, one gains the impression that the traveler must have been constantly on the move. And when it is remembered that the major part of this time was spent either in the southern hemisphere or in the equatorial regions of the world, where in many cases, somewhat slow and primitive means of locomotion exist, one must conclude that the lately completed journey of Ernest H. Wilson, noted plant collector and assistant director of the famed Arnold Arboretum of Boston, must have been a long and rather arduous one, although different from the several expeditions undertaken in western China for James Veitch and Sons of London, and the Arnold Arboretum.

Having gained valuable experience in successive expeditions undertaken in Formosa, Korea, Manchuria, western China, and Japan, during the course of which he added no less than 1193 species and varieties of woody plants, hundreds of which are proving most valuable garden plants, since their dissemination throughout the world's temperate zones, Mr. Wilson was well fitted to undertake his last world tour, not for the purpose of collecting seeds and plants, but to secure dried specimens for herbarium uses of many plants doomed ere long to extinction owing to the progress of civilization; to get in touch with correspondents of the Arnold Arboretum in various parts of the world; to establish means of mutual help with collectors and authorities; to effect exchanges with institutions and collections to the end that the herbarium of the Arnold Arboretum shall possess specimens of every woody plant on earth.

Leaving Boston on July 8, 1920, Mr. Wilson first went to England and crossing to France, sailed from Toulon for Freemantle in western Australia, by way of the Suez Canal and Ceylon. After touring western Australia he took the transcontinental train for Adelaide in southern Australia, and thence to Melbourne and Sydney. Next he sailed for New Zealand and arriving at Auckland, toured the length and breadth of that country by train or motor car. From New Zealand he went to Tasmania, and after a short stay there, returned to Melbourne, and from there to Brisbane in Queensland.

Next Mr. Wilson went by steamer to Thursday Island and Port Darwin in northern Australia; sailing from there for Java, and having crossed that wonderful tropical island, went to Singapore, Penang and the Federated Malay States, staying over at the capitol, the new city of Kuala-Lumpur. From Penang he sailed for Calcutta, calling en route at Rangoon in Burma. From Calcutta, he went through northern India via Lucknow by way of Dehra and Simla to Rawalpindi; thence to Kashmir, returning to Calcutta by way of Lahore, Delhi, Agra and Cawnpore. Again leaving Calcutta he went to Sikkim and Assam, and later went south from Calcutta to Ceylon via Madras, returning by the west coast of India to the Nilgiri Hills, thence to Bangalore and Bombay.

Africa yet remained to be conquered. Sailing from Bombay, Mombasa on the east coast of Africa was reached, and from there, Mr. Wilson went into the equatorial regions by way of Uganda to the sources of the Nile and the Venia Mountain country. Returning to Mombasa, he took ship to Beira in Portuguese East Africa; thence to Zanzibar and Dares Salaam. From Beira train was taken through southern Rhodesia and to the Victoria Falls on

the Zambesi, falls twice as high as Niagara and carrying about the same volume of water; next southward by train to Pretoria, the Transvaal capital; thence east and south through Bloemfontein to Port Elizabeth and through Cape Colony to Cape Town. From Cape Town, steamer was taken to England and later from England to the United States which was reached August 24, 1922.

Everywhere the traveler received a warm welcome, the very name of the Arnold Arboretum seemed to procure for him special attention, for news of his coming had preceded him.

Australia Mr. Wilson described as a vast and lonely continent, possessing great resources but rigidly limited in its development by lack of labor, which the Labor parties there will not admit. Much of Australia is potential cotton country. Western Australia resembles California and our arid West. New Zealand like Oregon and Washington is green, fruitful and beautiful, while Queensland, one of the best Australian states, although given to extreme labor policies, is tropical or sub-tropical. Western Australia is mainly a grazing country while southern Australia is a great grain-producing region.

In Queensland, much of the world's cotton could be produced but for the labor shortage. The whites will not tolerate the admission of the yellow or black races. The white man says he will do all the work, but he cannot do so. He succeeds for a time but eventually production fails. So with the white woman. In such a warm climate she cannot successfully perform all the household tasks falling upon her and at the same time, produce healthy children. The white race seems to be writing its own death warrant in refusing to have the assistance of the black and yellow races.

The happiest and most contented people in the world are the New Zealanders. Their beautiful and rich country produces about everything desirable in climate and crops, and here while no one is very rich, there are no poor. Their labor rule is much less fanatical than in some of the Australian states.

Australian trees are rich but strange. The *Eucalyptus* is the characteristic and predominant tree. Western Australia has the "grass tree" or "black boy," a tree with a frowzy top, somewhat resembling a palm in the descending masses of grass at the top and waist. Wood of the jarra tree, *Eucalyptus marginatus*, is specially valuable as the wood makes splendid paving blocks. The Karri or "marble trunk" sometimes reaches the height of three hundred feet, standing in great columned rows with a limitless carpet of bracken. The interior of Australia is an arid region and in a large measure treeless.

Amongst the exotic pests troubling Australia is the American prickly pear, or *Opuntia* which shows a disposition to take entire possession of the grazing lands, and which seems impossible of eradication. In New Zealand blackberries overrun fields and meadows, while water cresses choke ponds and streams. The rabbit pest continues unabated, but an enormous number are killed annually and exported in a frozen state.

The African baobab tree occurs in northern Australia. In Queensland a curious vegetable feature is the bottle tree, *Brachychiton rupestris*, which not only looks like a vast bottle standing on the ground but also yields drinkable water when tapped like a maple tree. The baobab while huge and imposing possesses wood which is almost

(Continued on page 295)

SCENTED MUSK

COINCIDENT with my note appearing on page 234 of the GARDENERS' CHRONICLE, comes a letter from my friend, J. M. Bridgeford. He says that a few years ago he discovered in a Devonshire cottage window one or two plants of the true scented musk and he persuaded the owner to let him have one. For some time it did yield scented progeny but the perfume is now entirely gone. He add, "I wish we could place our hands on a little of the good old type." Now, *Florum Amator*, it's a case of dig in and find that scented musk. T. A. WESTON.

Florum Amator has no reply to make to the frenzied ejaculations with which T. A. Weston opens the continuance of his discussion on Scented Musk, in the August issue of the CHRONICLE, for *Florum Amator* is not strong in that style of argument. He is, however, willing to discuss the subject in a scientific way, basing his argument on an array of facts and leaving out all personal experiences, against which courtesy always forbids a man to argue, and all personal references to friends, and disparaging remarks about Yankee seedsmen, a class of merchants of high business character, we think.

The real question at issue is this, was there ever a plant named *Mimulus moschatos*, which was musk scented, which is now extinct, or which is still extant but has lost its musk scent. That this plant has become extinct in a certain country, England for instance, is possible, but not probable, but that plants of *Mimulus moschatos* which were once musk scented in their native habitat or in cultivation, have lost their scent, we think highly improbable and, indeed, hardly possible.

It is customary to reason from analogy. The several species of Pelargoniums, namely, *P. capitatum*, the rose; *P. graveolens*, the lemon-scented; *P. vitifolium*, the balm-scented; *P. tomentosum*, the pennyroyal; *P. gratum*, the citron-scented; *P. odorata*, the apple-scented, were all scented when introduced, some of them one or more centuries ago, we are told, and they are scented now. Passing from the scented Pelargoniums to plants of other genera, we know that the *Aloysia citriodora*, lemon-scented verbena, introduced in 1784, is lemon-scented now just as it was in our boyhood. The same is true of *Hedeoma pulegioides*, American pennyroyal; *Mentha pulegium*, the true pennyroyal of Europe; *Mentha piperita*, peppermint, and *M. viridis*, spearmint. Leaving the plants having a scented foliage and turning to those which had sweet-scented flowers years ago, we find them with sweet-scented flowers now, e. g., *Nympha odorata*, the water lily; *Hemerocallis ava*, the lemon-scented day lily; *Polygonum tuberosa*, the tuberose; *Citrus sinensis*, the orange, and *Philadelphus coronarius*, the mock orange. We might easily add to this brief list of plants with scented foliage or with scented flowers, which were scented as far back as the records go and are scented now, but we think that this is sufficient to give force to our argument that if there ever was a *Mimulus moschatos* or a variety of it, that was musk-scented, that same species, or a variety of it, is musk-scented now. If, on the other hand, there was a species or variety of *Mimulus* which was not musk-scented years ago, which by carelessness or error has been propagated instead of the musk-scented variety of *Mimulus*, and has largely taken its place, that species or variety is probably without a musk scent now.

We may be mistaken in this matter; we do not belong to the very sure class of men who never will admit that they are wrong. We would be pleased, however, to have T. A. Weston submit a list of moderate length of plants which years ago had scented foliage, or scented flowers,

but whose foliage or flowers are now scentless, in support of his contention that a plant, e. g., *Mimulus moschatos*, was once scented but is now without scent. May I suggest that in this discussion of a subject which is very interesting, at least to *Florum Amator*, that we leave out all personalities and personal experiences, and any flings at either American or British seedsmen, for both of whom we have great respect, and simply present facts? *Florum Amator* does not care to continue the discussion about *Mimulus moschatos* in any bitter or unfriendly manner, and as he has said before, admits that he may be wrong in his conclusions. If so, he is ready to be convinced of his error by an array of facts.

FLORUM AMATOR.

I notice on page 234 of your valued paper that T. A. Weston has not seen the musk plant, either cultivated or wild. If he would take the trouble to call at our place, I would be pleased to show him a number of plants growing vigorously in the greenhouse and will also show him a plant in Orange which has astonished me by wintering through last Winter, so that he can see at one time both a cultivated and a so-called wild specimen.

W. A. MANDA.

Let me join in the "scented musk discussion." I have nothing to say about musk from seed, but I remember it in England growing naturally in the garden, and when grandmother wanted a pot to keep in the house, we just dug up some of the creeping stems, filled the pot with soil, laid on the rhizomes, and covered with soil. When I was on the F. W. Vanderbilt place, Hyde Park, N. Y., nearly twenty years ago, scented *Mimulus moschatos* was growing naturally in one of the shrubbery beds, and if it has not since been eradicated, it is probably growing there yet.

ROBERT BARTON.

WATER GARDENING

(Continued from page 288)

plant. In Britain great success has been achieved with it in water as deep as two feet and in which the plant increases with great rapidity. The fact that it does well in that depth of water opens possibilities of using it in climates having colder Winters than prevail in Britain, so long as an inch or two of unfrozen water remains over its crowns.

As a rule the best materials for water gardening are those of our own country, although there are some species which have been growing here so long that they may be looked upon as citizens. Notably among the latter is the Japanese Iris, *Iris laevigata*, which is common in our flower gardens, but all its fine characteristics are increased to a remarkable degree when grown as a sub-aquatic; there are also several species of native Iris which have their habitat in swampy places.

Of all situations we have to deal with in beautifying home surroundings, we have the clearest guidance from Nature in the material which is best to use for the water side. However good in form and right in every way in relation to the landscape a piece of water may be, it is quite easy to spoil the effect of it all by the use of material, especially in the way of shrubs and trees, which has not the form and characteristics of those native to the situation.

With this, as well as with other special gardens, it is advisable for those who have not had opportunities of gaining experience to obtain the advice of an expert, both in relation to the formation of the piece of water, as well as in the selection of plants to use.

Ornamental Flowering Trees and Shrubs

CAMILLO SCHNEIDER, in the Magazine *Gartenschoenheit*, Berlin

(Continued from August Issue)

JUNE-BERRIES (*Amelanchier*) and Choke-berries (*Aronia*). In our European woodlands there is no blossoming shrub or tree that in May can vie with the June-berries of the United States. At this time, in the eastern States, there blooms before all others *Amelanchier canadensis* (*A. Botryapium*) and *A. laevis* (*A. canadensis* of the gardens); the last is immediately recognized by its broad and almost horizontal branching. It is particularly beautiful at the time of blossoming, with its pendant flower racemes and purple young leaves. But the genuine, almost perpendicularly branching *canadensis* has its great charms, as the blossoms, which appear before the leaves, are in thick nodding inflorescences covered with silky hairs. When in the thin woodlands *Cornus florida* also shows itself at the same time in its blinding white splendor, one can scarcely think of anything more surprising or impressive. How enchantedly did my eye look upon the May landscapes when I journeyed in 1919 from Washington to New York, after I had already stood in astonishment before many a shrub of these Spring blossoms in the vicinity of Washington.

Accordingly the *Amelanchiers* deserve more than any other woody shrubs to be naturalized in our country. Their native representatives, *A. rotundifolia* or *vulgaris*, with which I became intimately acquainted upon my excursions in the hill country south of Vienna, makes a much smaller appeal. Somewhat taller shrubs than ours are the American *A. sanguinea* and *A. ovalis*, both of which pass usually as *spicata*, the latter, with its erect berries, especially deserves this name and merits the greatest esteem.

Deserving of quite cordial recommendation is the choke-berry, or *Aronia*, which is generally classed with *Sorbus* or *Pyrus*. I still remember clearly the vivid impression which *A. arbutifolia* made upon me in the nineties in the Greifswalder Botanical Gardens when the purple orange of its autumnal foliage was glowing. The splendor of its coloring attracted me to my first attempt at writing for publication. No less charming is *A. melanocarpa* and *A. atropurpurea*, likewise native to eastern North America. The most beautiful of all, however, is *arbutifolia*, which holds its attractive red fruit far into Winter, while that of *melanocarpa* ripens as early as August and soon drops.

The family of fruits with pits or *Pomaceae*, to which the apples and pears, as well as the genera named last, belong, is not at all exhausted by the enumeration of these types. I make quick mention only of the quince, *Cydonia*, of the Japanese Pseudo-quince, *Chanomeles*, of flame red, which merits wider dissemination because of its fruits. *Pseudocydonia chinensis*, the Chinese quince, whose pink flowers are not too striking, but have a wonderful fragrance, and whose stems have bark that peels off like that of the plane trees, should come into consideration for warm sites.

An additional genus, large and rich in form, whose sorts for the most part, however, bloom late in the Spring or even in the Summer is that of the Mountain Ashes and Alders: *Sorbus*. They deserve, like the thorns, *Crataegus*, and the rock sprays, *Cotoneaster*, a detailed account for their many kinds and forms play a great role in the gardens, not only at the time of bloom, but also in the case of many, at the time of fruiting in late Summer and in Autumn.

For the present only brief reference can be made to

them. Among the mountain ashes, *Sorbus aucuparia*, the most noteworthy to me are the north Chinese *S. puhuashanensis* and *S. discolor* (*S. pekurensis*) but *S. splendida* also, a cross of the native *S. aucuparia* and *S. Americana*, merits its name. Our mountain ash with *S. aria*, has yielded the beautiful *S. hybrida* or *S. quercifolia* in which the variation of the leaf structure of mountain ashes so markedly expresses itself. Of the Asiatic group I have always prized *S. hostii* the most, which far excels both its parents, *S. Chamemespilus* and *S. Mongestii* in neatness. Very rich in bloom is the interesting east Asiatic *S. (Micromeles) alnifolia* also.

Among the thorns, *Crataegus*, we treasure in the gardens perhaps above all others the red and pink forms of the native *C. monogyna*. The darkest colored is known as Paul's New Scarlet, or *kermesimo-plena*. What a handsome effect these thorns make I have often realized in the wonderful Place of the Prison in Dresden, for which, to be sure, one might wish a still more pleasant garden arrangement. A still larger number of *Crataegus* are of importance as Spring bloomers, and in the first rank are the east Asiatic *C. chlorosarca*, *C. dahurica*, *C. korolkowii* and *C. sanguinea*. Among the hundreds of North American species we must first determine upon a selection suitable for us.

Very manifold are the rock sprays, *Cotoneaster*. As rich and handsome sorts from China and eastern Asia, I learned to know in the Arnold Arboretum *C. hupehensis* and *C. multiflora* var. *calocarpa*. I believe that these two are not equaled at their period of blooming by any other sort, to say nothing of their being surpassed. At the same time the latter is especially of extraordinary beauty when decorated with its vividly colored fruit and bears its name quite properly. But the charms of the blossoms of the types having smaller stature, like *adpressa*, *Dammeri* or *horizontalis* are not to be valued too little.

In conclusion, let me add a few words further about the adaptability of these beautiful flowering trees and shrubs in our parks and home grounds. They are still all too uncommon, and in only a few cases have I seen, up to the present time, the attempt to allow them their full effect. For this a particular effort ought to be made in our public parks which could make an essential gain in attractiveness thereby. There is, of course, needed along with this a certain education on the part of the visitors so that they do not wantonly break off the beautiful branches of blossoms, as too often, alas, happens even still in fruit orchards. We must acquire for these wonderful flowers the reverence of the Orientals. The sight of them must not arouse in us only an individual and selfish desire to possess; it must free in us a feeling of pure enjoyment, of devoted rapture. We must find in them works of art, before which we stand in admiration and full of inner feelings.

Let the cherries and the apples be introduced into our public parks, but not as detached specimens or in small scattered groups. No! in large, animated groups which at the time of blossoming would draw thousands, as they do in Japan, and as I saw was the case in the Arnold Arboretum also. There no one hindered the visitors from stepping upon the grass in order to look at them more closely. People reclined in the Spring sunshine around the blossoming trees and the impression upon the visitors was so deep that only seldomly a froward hand thoughtlessly

The Source of Plant Food

WILLARD N. CLUTE

IT is a difficult matter to convince the average individual that plants do not take their food out of the ground. Everywhere he sees vegetation rooted in the soil and naturally infers that this is the source of their nourishment. Moreover, it is a matter of common knowledge that plants absorb from the soil, for if water be withheld from any plant for a sufficient time, it invariably withers and dies. It is, of course, true that plants absorb water and mineral matter from the earth, but these are not foods in the generally accepted meaning of the word, though water or the elements of which it is composed form part of all food. Water must be combined with other elements before it becomes food, however.

Ordinarily foods are classed as carbohydrates, fats or oils, and proteins. Probably the commonest are the carbohydrates, represented by such substances as sugar, starch, wood or cellulose, and inulin. If the water is completely driven out of any of these, as in the process of making charcoal from wood, a black substance known as carbon is left. This is derived by plants, not from the soil, but from the air. This carbon exists in the air in very minute quantities combined with oxygen in the form of carbon dioxide. In ordinary air there are only about three parts of this gas in ten thousand and yet from such minute quantities, all the food in the world is built up.

Not only are the water and carbon dioxide the basic material from which food is made, but plants are the only organisms in existence that can tear the elements in these substances apart and re-combine them in the form of food. The plant world, therefore, carries the animal world with it as a sort of pensioner on its bounty. If all the plants should perish, the animals would soon follow them from sheer inability to get food.

The whole problem of animal and plant nutrition is bound up with the problem of securing energy. A small part of our food is used in growth and repair, but the major part is used in securing energy with which we move in carrying out a vast number of activities. This energy was stored originally in the food by plants, and the best that animals can do is to break down the food already formed and use the energy. Plants alone are able to accumulate and fix new supplies of energy.

All day long the sun showers down on the earth various forms of energy. Heat, light, electrical and chemical rays fall upon the plants, and the latter, by means of certain green bodies in the cells known as chloroplasts, stop and use certain of these rays. The heat rays seem most important in promoting or hastening various life processes in the plants, and only the light rays are sources of energy. It is well known that ordinary daylight is made up of at least seven colors and that these are sorted out in various ways to give the color effects that we see. An apple, for instance, looks red because it reflects the red rays and absorbs the others. Plants are green, therefore, not because they use green rays, but because they reflect them. The fact that plants are green is of no advantage to them; it simply indicates that in the green parts some of the light rays are being stopped. This explains the almost universal color of plants and the further fact that all independent plants invariably seek the light. Plants that are not green are unable to make use of the light rays and consequently are unable to secure energy from this source and are obliged to depend upon food made by other organisms, just as animals do.

In the plant the light rays are turned to a form of energy, similar to, or identical with, electrical energy, and

by means of this the carbon dioxide and water are combined to form starches and sugars. In making this combination a certain amount of oxygen is left over and this is generally given off to the air, which probably accounts for the idea generally held that plants breathe out what animals breathe in. In the process of respiration, commonly called breathing, plants behave exactly like animals, taking in oxygen and giving out carbon dioxide.

The reason the process of respiration in animals and plants is confused is that in food making, plants have a second process, known as photosynthesis, which animals do not have, and which is exactly the reverse of respiration, in fact this is no other than the process of food-making which we have been discussing. Photosynthesis, however, is so much more active than respiration in plants that it usually masks respiration and thus contributes to the idea that it is the only process.

There are only about ten chemical elements required by plants and only three of these, are concerned in food making and the storage and release of energy. Since these three are found in the carbon dioxide of the air and the soil water the farmer sometimes expresses it by saying that his crops are made of wind and water. It is well known, however, that sterile soils will not grow crops and that fertilizers must be added to most soils in order that plants will thrive. The fertilizers, of course, contain the other elements that are absolutely necessary to the well-being of the plants. Some of these are concerned in the ripening of wood and fruit, others are necessary in forming chlorophyll, still others neutralize acids, promote plant processes or contribute to the building up of the living substance or protoplasm. But the securing of energy and the locking it up until needed in the form of wood, coal, oil and food, is almost entirely a matter of wind, water and sunlight.

ORNAMENTAL FLOWERING TREES AND SHRUBS

(Continued from page 291)

broke off branches. The effect is the stronger in proportion as we plant larger groups of one sort and thus, according to the time of bloom, we can create changing Springtime pictures at different points of large public parks. For this purpose quite particularly there should be recommended the ornamental apples mentioned above, which, with their crops of fruit, give additional charm. This is true of the rock sprays also, and of the Aronias, whose Autumnal splendor makes them all the more valuable.

In small gardens we do not require the effect of massing. Here we can lend ourselves entirely to specimen plants and can bring quite close to us the many blooming types. A place may be found in even the smallest garden for the low growing *Malus Sargentii*, *Prunus japonica*, *P. humilis* and *P. triloba*, *Amelanchier spicata*, all Aronias, *Chanomeles* and *Cotoneaster hupehensis*. In gardens of medium size let us plant the double flowering Japanese ornamental cherries, the wonderfully beautiful *Malus Halliana Parkmanii*, *M. ioensis fl. pl.*, *M. Sieboldi*, *M. theifera*, *Cotoneaster multiflora calocarpa* and yet many others of the kinds mentioned, each one of which produces a lovely sight by itself. He who once begins to make friends of all these forms will thereafter always more zealously strive to help introduce them everywhere.—

F. B. M.

The Greenhouse, Month to Month

GEORGE F. STEWART

THIS month the chrysanthemums will be the chief attractions. They will be flowering profusely from the last of October until the middle of November. Of course, some early varieties will have gone by, and late varieties will straggle along until the first of the year. It is interesting to note the great change that has taken place toward the chrysanthemum around Boston. Fifteen to thirty years ago, the fashion was for large blooms, and enormous specimen plants. Of late years, on many private estates there has been a distinct reaction, and smaller plants without disbudding are called for. Also one will see on some places, three stems run up in a seven- or eight-inch pot, three to four feet, according to the variety, and then a spray of flowers on each stem. These plants are very effective for using in high windows in the house, and are just as useful for cutting for vases. They also appear more natural than the enormous single flower, which as one lady said to me, reminded her of a floor mop. I believe, however, that in certain positions a vase of large bloom are very effective, and show the grower's skill. In our exhibitions here in Boston of late years, there has been very few large specimen plants exhibited, and very few large blooms in vases. Some very effective groups, however, have been put up, arranged with other plants. The greenhouse man's aim should be to suit the taste and ideas of his employer.

This is a good time to weed out undesirable varieties. There may be shades of color that do not appeal to the family and some of the newer varieties may be considered better than the older ones. While they are in flower, it is better to take note of these things and know what and how many of a given variety may be grown another season.

Careful watering of chrysanthemums must be done as the flower begins to open. By the afternoon the floors should be dry and a nice dry atmosphere maintained over night. The earlier flowering varieties may be moved away from the later ones, if they are grown in pots, when syringings may be given them to keep red spider in check. We have seen this destructive little insect destroy the later flowers, before they were ready to cut, when they were planted out on a bench carelessly among the early flowering ones.

In the cool greenhouse more careful watering must be done among the hard wood plants as the day shortens. If there is anything that these plants will not stand it is careless watering. It is no use in putting any man who has no love for these plants to look after them, and he must likewise have had experience among them. It may be that, because of these exacting requirements, so few of these once popular plants are seen around nowadays. I refer especially to such plants as *Bauera*, *Pimelea*, *Eriostemon*, *Luculia gratissima*, *Daphne*, Heaths, etc. Every gardener ought to familiarize himself with the culture of these plants as there are none that are handsomer when they are well grown. Many of our young men need training as to their requirements, and it is up to the older generation to see that they are taught.

Any cyclamen plants that are to be kept for late work in March, may be given their final shift this month, and brought along in a cool house avoiding draughts. A good compost is one part nice fibery loam; one part flakey

leaves, preferably oak or beech; a little dried cow manure; enough sharp sand to keep the soil porous; also a sprinkling of broken charcoal. Fumigate at least once a week with some of the tobacco remedies. Hydrocyanic gas may be used by an experienced person. We have found that it is cheaper, more effective, and does not need to be done as often as with the nicotine remedies.

Primula obconica can be had in several shades of color. Many object to the magenta shades, but the whites and blues are fine. Some cannot handle this plant without getting poisoned. Personally, I cannot touch it. I can well remember, as a young man about thirty years ago, a very unreasonable gardener whom I worked under, insisted that I handle it. My hands and arms were a sight. Everyone should be warned about this danger, especially if used for house decoration. These plants may get their final potting this month, using a good rich loam. All primulas can be kept in cold frames for quite a while yet, if the frames are well built. The greenhouse is likely to be crowded until the chrysanthemum season is over. A mat over the glass will generally keep out all frost until well into November.

Some of the larger hybrid calceolarias ought to be fit for nine-inch pots in early November; that is, if they were sown in April and moved right along. Keep them in the coolest house and as close to the glass as possible. The finest specimens I have ever seen, were all the time, from first of October until they threw up their flower stems, kept so close to the glass that one could merely pass the open hand between the glass and the plant. Of course, they had to be lowered gradually as they grew.

Fuchsias that are intended for what we call half specimens, in nine- and ten-inch pots next May, should be in five-inch pots in early November if they are doing well. Pinch and shape them as advised in an earlier article, and keep them in a night temperature around fifty-five degrees.

Annuals such as *Calendula*, *Dimorphotheca*, lupines, snapdragons, stocks, that are wanted for Winter flowering, must not be allowed to get into a starved condition. If they are grown in pots, move them along until the desired size is reached. If they are to be planted out on a bench, say after chrysanthemums, it is better to give them a small shift rather than that they should suffer. We have sometimes kept up the vigor by knocking them out of the small pots and setting them in flats. Sprinkle a very thin layer of rich loam over the bottom of each flat before setting the plants in them. We have kept them this way in good condition from two to three weeks.

Carnations that have been bench-grown will now be giving fine flower stems, and the bench will be full of roots. See that a little stimulation is given occasionally. We have used Clay's fertilizer successfully, and sheep manure scattered over the surface of the bench for a change. A friend of mine, who is a very fine grower, tells me he uses tankage in slight applications with success.

As the days shorten, the rosehouse needs careful watching as regards air and moisture. Over night have all moisture dried off the leaves after syringing and the floors dry also. Keep the soil on the bench in a fairly moist condition at all times. Experience has taught me,

under our conditions, that we have less black spot to contend with by keeping the soil around the plants on the moist side, rather than on the dry side.

To those who have plenty of bench space, vegetables may be grown from November on. Beans, carrots, beets, New Zealand spinach, lettuce, etc. are always acceptable in a young tender state. They can be grown successfully in a night temperature around sixty degrees with a ten to fifteen degrees rise during the day. Lettuce will do better in a lower temperature. Tomatoes, of course, are always acceptable if one gets a good forcing variety and careful cultivation is practiced.

Now is the time to begin fighting mealy bug on the grape vines, and scale insect on the fruit trees indoors. In my opinion there is nothing better than Hydrocyanic gas. There is a nice little booklet that can be had from the Roessler & Hasslacher Chemical Co., Perth Amboy, N. J., telling in an up-to-date manner how to use it. They also supply cyanide in one ounce egg-shaped pieces which are most convenient. If the gas is used according to directions in the booklet, every two weeks while the fruit trees and vines are dormant, there will be very little trouble in the growing season with bugs and scale. If, however, they have been badly infected over a period of years, one season will not eradicate them. Also after we have them clean, we still keep it up, for although we see no signs of these insects, prevention is better than

cure. I have used this gas for a great number of years, (in fact, ever since it began to be known on this side of the Atlantic) on a great many different kinds of plants, and consider it one of the greatest time saving fumigants known to the greenhouse man. There are a number of plants which will get slightly injured with it, and one has to learn by experience what to eliminate from a greenhouse when using it. I would never think of using it on orchids, as everytime I attempted it they were injured. George Pring, of St. Louis, told me they can use it on these plants out there without injury to them. Atmospheric conditions may have a good deal to do with it.

Cattleyas *Bowringiana* and *labiata* are in sheath and pushing up their flowers. They have to be carefully watered, and we find after cutting the flowers of *C. labiata*, which should be done with a clean cut, it is better for some time to keep them in a rather dry atmosphere until the cut dries. After the flowers are cut, if kept in too moist a condition, the bulb of this cattleya is apt to rot. *Dendrobium Phalanopsis Schroederianum* is also flowering. We find it does well in a temperature never lower than sixty degrees. It propagates readily. We got a small offset from a friend about seventeen years ago, and have raised eighteen plants from that one piece. The flowers are one of the most useful and decorative of the orchid family.

Work for the Month in the Garden

SAMUEL GOLDING

NOW that the majority of crops has been gathered in, there remains but a few weeks ere Winter makes its reappearance. However, much can be accomplished during open weather toward laying the foundation for next year's crops. The breaking up of new ground, digging and trenching; mixing the subsoil and incorporating some good farm yard manure. When this is well done it has a most important bearing on the success of the crops, as it provides for more depth and a more fertile rooting medium, which will help the various plants to withstand the heat and draught of Summer. Any subsoil brought to the surface will receive the mellowing influence of the Winter's frost. This work, if done now, will save valuable time when the Spring rush is here, for it will then need only raking and leveling to be ready for the reception of seeds or plants.

Complete the lifting of late potatoes and other roots, storing them away for Winter use. Make preparations for forcing asparagus, seakale, chicory and rhubarb; lift a few roots and keep them as cool as possible. They respond more readily when brought into heat, if they have been subjected to some frost. Cut over the asparagus bed, as soon as the stems are ripe, and fork in a good coating of manure, which will save time in the Spring.

If severe frost threatens, lift cauliflower and place close together in a fit, deep frame, or cool shed where it will keep for a considerable time. Lift late endive and lettuce and place in cold frames; failing this means of protection, use some salt hay or other material to cover them during frosty snaps.

Remove the bottom foliage from the Brussels sprouts to give the growing sprouts all light and sunshine during the brief growing season that remains. This is a vegetable whose importance and value is oftentimes overlooked during the days of plenty, before a killing frost takes

away the more tender. It requires a good season growth and will be much appreciated at this time. Clean up and burn all decaying foliage and vegetable matter.

Finish earthing up late celery, which should be done by the end of October or early in November, as we may experience severe frost. When well banked up it is quite safe. Make preparations for its removal to Winter quarters in November. If wintered outside, collect material for protection in case of an early emergency.

Make up Mushroom beds for Winter bearing. Late vegetables growing in frames will need careful attention, regarding the watering and ventilating. Have a supply of mats on hand for covering the sash on cold nights.

As soon as the Summer bedding has been cut down, begin preparations immediately for the Spring flowering bulbs. Get the tulips, hyacinths, narcissi, scillas planted when preparing the beds for their reception, avoid too heavy a coating of manure. If they were well manured in the Spring it should be sufficient.

If hardy Lilies are ordered from the dealer, arrange and prepare the location for planting them. Give the ground a dressing of leaf soil. In case of late delivery, cover the ground with some protection to prevent it from freezing up, so they can be planted as soon as they are received to prevent any shrivelling of the bulbs.

The Hardy Chrysanthemum continues gay throughout the month. The recent spell of warm weather has improved them. They should have some protection on cold nights. Lift dahlias, cannas, gladioli, and allow them to dry outside before storing. If ordinary wooden labels are used to label them, attach the labels to the tubers with a piece of wire.

When string is used, it oftentimes decays and causes confusion of names when they are brought out in the Spring. It is a good plan to store them crown downward, so that

any accumulated moisture can drain away through the stalk. If they are placed in a frost-proof cellar, they usually keep alright, but will need some attention. If placed in a cellar where there is a furnace, the dry atmosphere may cause the bulbs to shrivel. This can be prevented if some simple precaution is taken to guard against it, such as a light covering when shrivelling is detected.

If any alterations or rearrangements are to be done in the flower borders, it should be done in October, if possible, while some root action can be made. When November is here the soil loses heat, and the time is too short for the plant to become established. If, however, it cannot be accomplished before that time, it is best to postpone dividing and transplanting until the Spring.

Cut back somewhat the long and straggling growth of the hybrid teas and hybrid perpetual roses, which prevents some damage from winds and storms.

This is a good time to secure any stock of roses for Spring planting. They can be laid in and protected during the Winter, and will be on hand when wanted next season.

The clearing up of leaves will take up a lot of time these days, and they should be carefully stored away for making leaf soil, or for use in protecting rose beds or other subjects.

Keep the lawns trim until the growth ceases; after that, have the mowing machines thoroughly overhauled and put away in readiness for next year's work.

Plant deciduous trees and shrubs. Prepare holes for the reception of apple and pear trees so that they can be planted as soon as they are received from the nurseryman. Plant firmly and stake securely. A good mulch will be beneficial to the newly planted stuff and will protect the roots during Winter.

AN ARNOLD ARBORETUM PLANTSMAN'S WORLD TOUR

(Continued from page 289)

totally useless and is so soft that when the settlers made an attempt to get rid of one of the trees by cutting into it and introducing a heavy charge of dynamite which was exploded, the charge simply blew itself up through the tree as though it were so much water or air, leaving the tree still standing. There was not enough resistance in the pulp matter to give the explosive any hold.

In Java there are abundant tropical resources which a large and docile native population cares for, while coffee and cocoa are the leading products. Much rubber is also being grown, but the latter proves a mere bagatelle compared with what Mr. Wilson saw between Penang and Singapore in the Federated Malay States. For over seven hours, he rode at least three hundred miles through unbroken rubber plantations, and this illustrates the general tropical tendency of the substitution of cultivation for forest life and the consequent extermination of species.

Kashmir was found not less lovely than it is poetically reputed to be. Mr. Wilson was interested in visiting in the garden of Nazimbaugh across the lake from the capitol, Srinagar, the giant plane tree planted by the same Mogul emperor who built the famed Taj Mahal at Agra. This is none other than the oriental plane often seen in American parks. The famed Taj Mahal quite realized his highest expectations. In Assam he searched for that rare tree, the Khasya pine. At a point near Shillong, the capital of Assam, is the wettest place in the world with a rain fall of over six hundred fifty inches a year. In the Nilgiri Hills Mr. Wilson visited the sacred Bow tree, *Ficus religiosa*, under which Gautama Buddha sat when he received his revelation.

In Africa after passing through the big game country from Mombasa to Nairobi and reaching the Aberdare Mountains which are exactly under the equator but covered with perpetual snow, he slept one night at an altitude of 10,000 feet which while above the timber line was not up to the snow line. Mount Kenya, the loftiest of the range, reaches a height of 18,620 feet.

Much of the Kenya and Uganda region has a salubrious climate, is a "white man's country" and produces increasing quantities of cotton. There is also considerable ranching here and some Americans were among the ranchers. Many parts of Uganda are tropical. On Lake Victoria Nyanza, Mr. Wilson saw beautiful islands evidently once inhabited, and asking why no one lived there now, he was told that the sleeping sickness had killed every one.

On the equatorial mountains, Mr. Wilson found the great African juniper, *Juniperus procera* one hundred fifty feet high and twenty feet in circumference, a full brother of our common red cedar. The baobab or cream of tartar tree is abundant here; tree heaths are innumerable, and from these are made briar wood pipes; also tree lobelias of great altitudes and the famed "deadly upas tree," which by the way is not deadly at all and never was. It is as innocent of all detriment or offence as a rose bush or an apple tree. The carbon dioxide which settled in certain valleys and caused deaths among those who slept there, did not come from the upas tree. Under the sprays of the sublime Victoria Falls of the Zambesi, *Gladiolus primulinus* grows most luxuriantly, and with the unceasing clouds of mist this gladiolus appears to be continuously in flower.

The Monterey pine of California nearly extinct in America has been introduced in Cape Colony where it thrives most amazingly and promises to be of great economic value. The Monterey cypress also confined to a narrow strip in California has found favorable conditions for its development in Cape Colony. On the Lion's Head and spurs of Table Mountain is a most remarkable tree, survival of an earlier age in the world, the silver tree, *Leucodendron argenteum*, which is to be found nowhere else in the world. The silver tree while resembling no conifer, bears as its abundant fruit, cones each as big as a large tea cup. The cone is covered with seeds, each of which has on its top a fleecy arrangement of wings or "planes," more or less twisted or involuted like the blades of a ship's screw propeller. At the moment when in the process of ripening the seed is detached from the cone, the pod opens and the black seeds about as large as a pin, drop to the full length of a black cord about an inch long. The wings of the propeller now catch the wind and the "parachute" starts off on its aerial journey to be deposited at last where it is expected to germinate. It greatly surpasses in complexity and beauty the maple and linden, but alas, this marvelous contrivance goes for naught. The silver tree belongs to the banished geologic past. Newer growths have crowded it out and offer it apparently no chance whatever.

In Cape Colony are five hundred varieties of ericaceous plants; whole hillsides of *Erica melanthaia* in four colors make wonderful pictures. Here *Amaryllis belladonna* abounds and blossoms better after severe fires have swept over the land. *Disa grandiflora* on the dripping cliffs of Table Mountain well earned the title of "the pride of Table Mountain." South Africa is a white man's country and the resources are enormous. In South Africa, as elsewhere, Mr. Wilson received a most cordial welcome, not only from forestry and conservation authorities, but from the government authorities who gave him every facility and paid him much honor. The fame of the Arnold Arboretum, its collections and resources, had gone before him.

Departments of Foreign Exchange and Book Reviews

ON "HARDENING PLANTS."

FEW garden practices are so universally followed by good gardeners or so little understood by anybody, as is the practice of hardening plants. Everyone who raises plants under glass knows that to transfer them directly in the early part of the year from the heat in which they are grown to the chances and changes of temperature in the open is to court failure. Gardeners also know that the hardening process is somewhat slow and that one or two days only in a cold frame does not suffice to harden young plants. Experiments carried out a few years ago by Mr. Harvey*, show in a most interesting manner that although the hardening process begins at once when plants are transferred from greenhouse to cold frame—in one day the plants acquire some measure of increased resistance to cold—yet at least five days elapse before the plants become really hard. Thus Cabbage, after five days' exposure to cold frame temperature—three degrees above freezing—were able to resist thirty minutes' exposure to 3°C., although the temperature froze them stiff and killed outright unhardened plants. He also showed what is of great interest to gardeners in this capricious climate, that hardened plants lose under warm conditions their hardness is about the same time as they acquire it. If, therefore, tempted by a genial spell of weather, the gardener puts out his hardened plants, and if that genial spell lasts long enough to make the plants soft again, they are almost as prone to damage as they would have been had they not been hardened at all. "More haste less speed," is the motto to observe in planting out. Physiologists who have investigated the effects of frost on plants have given us a good definition of hardness. It is the ability to survive ice formation within the tissues. Of our garden plants the tender ones do not possess this power, and we know of no means of making them acquire it. Some possess it, as it were, naturally; others, and they are the ones that interest us here, may acquire hardness. The Cabbage is an example of this last class, whereas the Tomato cannot be "taught" to resist a temperature below 5° Centigrade. The adept in gardening can tell by the appearance and still more by the "feel" of a plant, whether it has been well hardened. This is due to the fact that during the hardening process growth is checked and hence leaves and soft stems, instead of appearing sappy, have a stiffish appearance and are springy and elastic. They are smaller and thicker than are those of unhardened plants of equal age. Experiment has shown that hardening may be assisted in watering plants with solutions which check growth. Give them nitrates such as potassium or calcium nitrate and the plants' growth is stimulated. They become sappy and soft, but water them with a weak solution of common salt or washing soda (at the rate of about two oz. to the gallon) and their hardness is increased for the same reason that it increases in the cold frame, namely, because growth is checked. Withholding water is, of course, another means of aiding the hardening process. It follows from what has been said, that age is a factor to be taken into account. Young tissues, for example those of leaves, are more easily injured than are older tissues; a fact which has to be borne in mind in Autumn sowing and Autumn planting. There are apparent exceptions to this rule; for example, July sown Beet may be left in the ground, if the soil be not a very wet one, well into the Winter, by which time old roots would have perished. This, however, is to be attributed to the fact that the "root" of the mature Beet consists of tissues, the cells of which are on the down grade of life, they are, as it were, over-mature, and begin to show the reduced resistance of old age. Plants which are hardy in the sense in which the word is used here may show signs of "frost-bite," although they do not succumb to a hard frost. These signs—also exhibited by tender plants when grown in too low a temperature—take the form of spots on the leaves. These spots are at first translucent, owing to the fact that they represent areas in which the inter-cellular spaces, normally full of air, have become injected with water that has been excreted from the neighboring cells as a result of the low temperature. Even hardy plants may show these frosted areas, but in their case the frost spots disappear, whereas in tender plants they become brown as the cells disintegrate. Some hardy plants, like the Cabbage, show curious "frost-bite" in the spotted areas. As Mr. Harvey has shown, such frost spots, in the course of a few days to an embossed area of a color lighter than that of the rest of the leaf. These

intumescences go on growing and may reach a large size, and a Cabbage leaf which has been exposed to and recovered from frost, may have its surface puckered and rolled in most fantastic shapes. This behavior may be likened to that often produced by mechanical injury and the formation of those intumescences must be referred to the plant's reaction to the wound-stimulus of frost. Bloom on the leaf often serves, as may be shown by observing different varieties of Cabbage, to prevent injury from frost. This, according to Mr. Harvey, is probably due to the waxy layer acting as a water-proof preventing communication between water on the outside of the leaf and that lining the cell walls and occurring in the cells. When frost comes, the water on the leaf-surface is cooled and in the absence of wax this cooling is transmitted to the water of the cell-walls and cells. As the process continues, this water is undercooled. It does not freeze, however, unless the ice crystals which form on the surface are in continuity with the water in the walls and cells. The bloom breaks the continuity and hence ice—which is the danger—forms less readily in a leaf with bloom than in one without it. There are numerous hypotheses as to the actual cause of death from freezing; the most probable is that as water escapes from the cells, the nitrogenous complex compounds (proteins) on which cell vitality depends are salted out, that is, precipitated, and that once this process has been set up, recovery is impossible, because the vital mechanism has been destroyed. Hardening on this hypothesis is due to a change in the composition of the proteins of the cell. During the process of hardening these substances give rise to other proteins of simpler construction which are less apt to be salted out, that is, thrown out of the vital mechanism.

It is common practice to spray plants which have been subjected to frost. The practice is a good one, but how it achieves the end is obscure. It was thought at one time that it caused a slower thawing and gave time to the cells which had lost water to recover it. In point of fact, spraying hastens the thawing process and it seems more probable that its good effect is due to transpiration being checked. Mr. Harvey has made a curious observation which lends some collateral support to this view. He finds that if the leaves of a frost-spotted Cabbage are submerged in water, the intumescences already described do not develop. Water appears, therefore, to arrest the pathological processes set up by frost and the recovery of a frosted leaf which has been sprayed must be included in the already long list of "water cures."—*The Gardeners' Chronicle* (British).

PLANT PESTS AND THEIR PREVENTION.

THE large amount of space in gardening papers devoted to plant pests and remedies for their extermination would seem to indicate that enemies to plant life are becoming a serious menace to horticulture. Assuming this to be a recognized fact it might not be amiss to try and find causes for this increasingly serious state of things. There are at the moment many capable men who are engaged in the praiseworthy task of finding remedies for the various troubles which constantly threaten with disaster the efforts of gardeners in the production of healthy fruits and vegetables. The plan adopted by these painstaking laborers is to work out the life-histories of the various fungi and insects which prey upon plants, and, having ascertained their weakest and most assailable parts, to provide weapons to overcome and subdue them. The scheme is a perfect one, and gardeners are indebted to them for their labors. But it seems to me, and it will appear equally clear to the reader, that gardeners and cultivators are very much to blame for the increased prevalence of plant foes, and it may be reasonable to suggest that they may do much to back up the efforts of the plant doctors by taking increased preventive measures.

The old saying, "Prevention is better than cure," has become so much of a platitude that it has lost much of its significance, but the truth of the saying is of such paramount importance to the gardener that he might well make it the leading maxim of his vocation. There are, of course, certain fungus diseases which occur in the form of epidemics, like the visitations of the dreaded Potato disease, while certain forms of aphid will develop to an alarming degree in time of drought. These attacks, so far as prevention is concerned, are more or less beyond the control of the cultivator, who must needs rely on the aid of the plant pathologist to successfully combat them. On the other hand, the increase of many plant diseases and pests might be considerably

*"H. G. Harvey, 'The Effect of Temperature on the Development of Frost Injury' *Journal of Agricultural Research*, N.Y., 2, 1918"

checked by the more careful conformation to natural laws on the part of the gardener.

Take the case of that common disease among young seedlings known as "damping off." Millions of tiny plants are lost annually on account of this virulent fungus pest. But I believe, and most gardeners will be ready to admit, that in ninety-nine cases out of a hundred the attacks might be averted by adopting common-sense methods of culture. The disease is primarily one which attacks plants grown under artificial conditions. As every gardener knows, it attacks seedlings under glass and is caused either by overcrowding, excessive moisture, or a close, vitiated atmosphere. Another cause not always recognized by gardeners is that of sowing seeds in soil which has previously contained diseased seedlings. The preventive precautions in regard to the first-named causes are obvious, while the importance of sterilizing affected soil is equally evident. The above is a concrete case of a more or less preventable disease, but it is typical of a host of others. The matter of contagion is one which is very often too little considered by gardeners. A single plant in a greenhouse which is attacked by green-fly is capable of ruining a houseful of plants and is too often allowed to do so. One midewed plant is equally capable of inflicting damage, and frequently does so. These remarks seem so obviously true that it appears foolish to make them, but it is surprising what a large number of people will not take the necessary steps to isolate infected plants. The negligent gardener who fails to treat promptly the diseases which attack the fruit trees and crops in his garden is a menace to his neighbors. No conscientious grower, on however small a scale, will knowingly disregard the importance of checking diseases which might cause havoc to other people's crops. To take immediate steps for the eradication of injurious pests is a duty which belongs to every citizen. The matter of prevention is equally important, and the keynote of success may be briefly summed up in the words "good cultivation."

Apart from the more or less preventable causes of disease in cultivated plants, there are those which are probably due to what may be called "unnatural, common horticultural practices." In making a conscientious inquiry into the reasons for increased disease among plants, we cannot honestly shirk investigation into this side of the question. The practice of unduly forcing plants to produce flowers and fruit before the normal season is possibly responsible for the weakened constitution of many plants. This impaired vigor undoubtedly makes plants more susceptible to attack. Then, again, the continued propagation of plants by cuttings or buds may be another cause. Is it reasonable to suppose that the prolonged perpetuation of the same stock has anything to do with increased susceptibility to disease? The Potato is subject to something like seventeen different diseases, and few plants have been so subjected to vegetative reproduction.

Finally, it may not be amiss to inquire how far excessive plant breeding is responsible for increased plant sickness. I believe it is more or less allowed by most gardeners that those plants which have been the most subject to the work of the hybridist are the ones most prone to disease. It is a matter for speculation whether the high types of perfection seen in the so-called florists' flowers are to be paid for by an increased susceptibility to disease. The reckless crossing and intercrossing of many flowers has resulted in a diminution of seed production, and when we remember that the primary object of the flower is to perpetuate its species by means of seeds, we are brought face to face with the fact that we are hindering one of Nature's chief schemes for race perpetuity. To thwart Nature is to court disaster. We know this to be true in the case of the human body. In venturing the opinion that in our headlong race after abnormal types of flowers we are possibly depriving the generations yet unborn I do not attempt to dogmatize. My remarks on this head are suggestive only. I am content to leave the matter for consideration by wiser heads than mine.—*Gardening Illustrated*.

BOOK REVIEWS.

Text Book of Pomology by J. H. Gourley, M. S. The Macmillan Company, New York. Upon its nearly 400 pages, this well composed book presents the "experimental and investigational bases of fruit growing on the physiological side." It renders valuable service by having collected and put into convenient form for students who have already had considerable instruction in the schools much of the experimental material that has been accumulating. The selection of the material seems at every point to have been made wisely, so that the earnest student may draw his own practical conclusions from the results of most authoritative experiments with pruning, the thinning of fruit, orchard soils, cultural methods, fertilizers, the improvement of fruit, its storage, and several other problems less vital. The presentation is reinforced by many tables, eight clear illustrations and forty "figures."

The non-academic person, without true scientific bent, might complain that it is hard to find in this work definite and reliable conclusions. He might wish that the author had concisely given

his summary of the theories and experiments relating to each topic in the form which is used at the end of the chapter devoted to fertilizers and manures. But the careful reader finds expressed in the body of the book, on every point, conclusions as definite as they discreetly can be, for different parts of the country and different conditions.—F. M. B.

Cyclopedia of Hardy Fruits by U. P. Hedrick, The Macmillan Company, New York. Even in the face of the "change from the growing of fruit for personal use and pleasure to the commercial orcharding which is taking place in America," it can be stated unqualifiedly that this volume ought to have wide circulation. Its accuracy of description and determination of synonyms are in fact invaluable. Only in a few cases has the author found it necessary to compile a description and his cautious compilation is always frankly marked. Yet the number of different hardy fruits treated is very large and none worthy of note for any part of the country seems to have been omitted. Even the less commonly used fruits, like the pawpaw and the barberries, have received adequate treatment. The at all serious faults of any variety are not unmentioned, though the effort in every case has been to give in detail full recognition to all qualities that are good in both plant and fruit. The 325 black and white figures help the verbal description as do the sixteen full page plates.—F. B. M.

THE MARKET NURSERY WORK SERIES, by F. J. Fletcher, F. R. H. S. Benn Brothers, Ltd., London.

The aim and the ideals of this series of six neat booklets, each of less than seventy-five pages, has been commented upon before in these columns. At that time the hope was expressed that the excellencies of the first two numbers would be matched by those of the succeeding. This hope has not been disappointed in the third volume, "Roses for Market," nor in the fourth, "Carnations and Pinks," nor in the fifth, "Orchard Fruit Culture." Anything else could hardly be expected from a man who during nearly fifty years of successful experience as a commercial nurseryman has been a progressive student also. He combines shrewd business methods with esthetic appraisal.

From these little books the American amateur as well as the professional gardener and nurseryman can derive much of value even though he may have good reason to doubt that "there are no roses (*i.e.*, rose plants) in the world equal to those grown in the United Kingdom." But the painstaking carefulness used by the English grower to make the production of plants most economical he might do well to read about as the English grower would do well to learn about budding on *multiflora* seedlings. National practices, habits and ideals of course vary considerably. Even the most devoted lover of pinks would hardly agree with the world's greatest poet in calling this "good old English flower" "the fairest of flowers." But in England it has much greater vogue than in America and there the carnation can be extensively grown out doors. Affection for the carnation and still more for the border pinks make it seemingly hard for the author to devote a chapter to the now deservedly popular *Dianthus Allwoodii*, which combines to a high degree the better qualities of its parents, the perpetual-flowering carnation and the old garden pink, some strains of which in England now flower through most of the Summer.

Volume V is an admirably condensed treatise sufficiently plain and complete to guide a skillful and patient gardener in making his own fruit-trees. It is particularly valuable for the attention paid to dwarf fruit-trees and to cordons, a subject to which, because of the comparative lack of area has been given much more attention in Europe than in America.—F. B. M.

Greatness of mind is not shown by admitting small things but by making small things great under its influence. He who can take no interest in what is small, will take false interest in what is great.—*Ruskin*.

OWNERS OF COUNTRY ESTATES

desiring to obtain the services of gardeners, thoroughly versed in all phases of their profession, and qualified to assume the responsibilities the position calls for, as superintendents or gardeners, should apply to the National Association of Gardeners, M. C. Ebel, Secretary, 286 Fifth Avenue, New York.

The association numbers among its sustaining members, the owners of some of the foremost country estates in America.

The association makes no charge for any service it may render to employer or member.

(See page 300.)

Famous Massachusetts Estates Visited

DURING the gardeners' convention some of the numerous estates near Boston were visited, the predominating features are here briefly described.

clude all appearances of artificiality. Among the plants growing along the waterside is a cross between *Lobelia cardinalis* and the *L. siphilitica*, giving a flower of intermediate color.

The main garden, which one comes upon quickly after turning a border of shrubbery, is given over to perennials in variety. Mr. A. E. T. Rogers is the gardener in charge.

ESTATE OF RICHARD T. CRANE, JR.

Castle Hill Farm, the estate of Richard T. Crane, Jr., at Ipswich, is one of the largest and most famous estates in New England. It is much newer than many of the other places on the North Shore, and its development has been largely in the hands of Robert Cameron, ex-president of the National Association of Gardeners, and for many years superintendent of the Harvard Botanic Gardens in Cambridge.

This is a regal home, with a beautiful mansion at the top of a lofty knoll, and surrounded by 2,500 acres of rolling land which makes a gradual descent to the sea. The estate includes one of the best beaches on the North Shore, and an exceedingly charming stretch of

Guests of Mr. and Mrs. R. T. Crane, Jr., on their estate, Castle Hill Farm, of which Robert Cameron, president of the National Association of Gardeners, is superintendent

ESTATE OF MRS. WILLIAM H. MOORE

There are many interesting features about the estate of Mrs. William H. Moore at Prides Crossing, but it is most noted for its willow walk. This walk is composed of willow trees which arch at the top, enclosing it completely except for the openings at each end and in the middle. The walk is about two hundred feet long, and is set with stepping stones arranged in irregular fashion. It extends along one side of the main garden and is as picturesque as it is unique. Another feature of this estate and one of even more interest to the experienced gardener is a combination rock and water garden set into a slope down which a winding walk leads to the garden of perennial plants. It is a very natural arrangement, an attempt being made to ex-

Conventionists passing through the gardens on the estate of Mrs. William H. Moore.

View of the Perennial garden, one of several especially interesting gardens at Castle Hill Farm.

sand dunes. There is a wonderful vista from the mansion to the water, with trees on each side. At the present time the planting is bordered by Norway Poplars, which, however, are not making very good growth, and are being gradually replaced by evergreens. At one side of the house is an immense swimming pool, the water for which is supplied by a battery of pumps in a special building. These pumps also supply water for the entire estate. In addition there is an elaborate private lighting plant.

The planting around the house consists of hundreds of noble trees supplemented by sunken gardens and a large arbutus maze, which is in superb condition. This maze was a novelty to many of the visitors.

A formal garden reached by a series of stone steps from the house terrace is entirely enclosed and is planted to perennials. At

A group of the guests of Mr. and Mrs. Henry Hunnewell on their estate, renowned for its rose garden, collection of rhododendrons, and specimen trees and shrubs.

one end there is a fountain, and a large group of marble statues. Since Mr. Cameron came to the place he has greatly improved this end of the garden by the use of fastigate evergreens planted close against the wall. There is an elevated walk around the garden, with supports for tub plants.

Passing through a loggia at the further end one descends another flight of steps to the rose garden, which is planted almost entirely to teas and hybrid teas. This garden is also enclosed, but the trees and shrubs have been cut away so as to make a complete vista from the upper end of the formal garden through the rose garden and across the open country.

Inspecting the vegetable garden of Castle Hill Farm, some of the critics remarked on the unnaturalness of this garden as there was not a weed to be observed anywhere.

A short walk leads to the highest point of land on the estate, where an overlook has been established above a large reservoir where the water is stored.

One of the most interesting features to many of the visitors was the vegetable garden, which is unusually large and exceptionally well kept. Mr. Crane is greatly interested in a hospital in Ipswich, which was erected with funds furnished by him, and which he keeps supplied in large measure with vegetables from this garden.

There is a modern range of greenhouses on the place, a big storage house, and a set of buildings where the work horses and a herd of Guernsey cattle are kept. Mr. Cameron has a beautifully appointed house for his own occupancy, and there are modern buildings for the other employees who live on the estate.

ESTATE OF THOMAS E. PROCTOR

The visitors were unable to get anything like a comprehensive view of the Thomas E. Proctor estate at Topsfield, because of the limited amount of time given them. On this estate is a large and

remarkably complete arboretum, one of the finest private arboreta in the country. Here many new and rare trees and shrubs are to be found. All the specimens, too, are labeled as carefully and accurately as in a public park. Another feature of this estate which has made it widely known is a rock garden of large proportions. This garden surrounds a pond, making the setting unusually charming. It is filled with a comprehensive collection of Alpine plants. This estate also has a large range of greenhouses where James Marlborough, the very efficient superintendent, has gathered together the finest collection of Winter flowering begonias in this country, many of which have been seen at flower shows in Boston and other places.

ESTATE OF MRS. GARDNER M. LANE

Few mansions on the North Shore are more beautifully situated than that of Mrs. Gardner M. Lane at Manchester. Standing as it does on the top of a high bluff, it overlooks the sea for many miles at a particularly beautiful section of the coast line. The gardens, reached by a flower-bordered walk, are terraced. The uppermost garden is very formal in its character, with a large pool as a central feature. Descending a flight of steps one comes to the perennial garden, where are several plants not often seen, including *Gaura lindheimeri* and a form of *Cimicifuga* which none of the visitors could name. Another descent leads to the vegetable garden below, where are also the greenhouses. The rocks used in terracing this garden were not laid in cement, but the

A view from the vegetable garden of Castle Hill Farm showing the sand dunes and ocean in the distance; also a corner of the farm buildings.

cracks and crevices were filled with good loam to make a home for plants of many kinds. James Scott is in charge of this delightful estate.

HUNNEWELL ESTATE

Few private places in New England are better known than the Walter Hunnewell estate in Wellesley. This estate was established many years ago, and the Hunnewell family has taken unusual interest in horticultural matters of all kinds. They have been in particularly close association with the Arnold Arboretum, and with plant hunters, the result being that the grounds contain many of the finest and most valuable ornamental trees and shrubs to be found in any private collection. The evergreens are particularly noteworthy. This estate is famous for its rhododendrons and azaleas. It was here that hardy rhododendrons were first taken in hand for general planting, and here, too, a number of new azaleas have been originated. A particularly interesting feature is the topiary garden planted many years ago. It borders the lake, and is overlooked by an observatory. T. D. Hatfield, the superintendent, is known the country over as an authority on horticultural matters.

The H. S. Hunnewell estate comprises 650 acres, and is noted especially for its wonderful expanses of fine greensward. It also contains a large number of trees and a splendid rose garden. John G. Duguid is the superintendent.

ESTATE OF LARZ ANDERSON

Probably the Larz Anderson estate in Brookline an attractive spot of which is illustrated on the front cover, contains the
(Continued on page 301)

National Association of Gardeners

Secretary's Office: 286 Fifth Avenue, New York

The aims of the association are, to elevate the profession of gardening by endeavoring to improve conditions within it.

To cement a closer bondship among all engaged in, and interested in, gardening—to create a greater confidence between employer and employee.

The association is professional in character. It must in no wise be associated with unionism.

President—Robert Cameron, Ipswich, Mass.
Vice-President—John Barnet, Sewickley, Pa.
Secretary—M. C. Ebel, 286 Fifth Ave., New York.
Treasurer—Montague Free, Brooklyn, N. Y.

TRUSTEES (For 1922)—William H. Waite, Arthur Smith, D. L. Mackintosh, New Jersey; W. N. Craig, Massachusetts; H. E. Downer, New York.

DIRECTORS (To serve until 1923)—Alexander Michie, Long Island; George F. Stewart, Massachusetts; Theodore Wirth, Minnesota; George W. Hess, District of Columbia; Daniel J. Coughlin, New York; John Barnet, Pennsylvania; Montague Free, New York. (To serve until 1924)—William Gray, Rhode Island; William Hertrick, California; George H. Pring, Missouri; Thos. Hatton, Connecticut; Robert Weeks, Ohio; W. H. Griffiths, Michigan; Thos. W. Head, New Jersey. (To serve until 1925)—George Wilson, Illinois; James Stuart, New York; William Kleinheinz, Pennsylvania; John F. Huss, Connecticut; Edwin Jenkins, Massachusetts; Carl N. Fohn, Colorado; Joseph Tansy, New York.

AN APPEAL FROM PRESIDENT-ELECT BARNET.

Dear Fellow Members:

The great honor that was bestowed on me at the Boston convention in electing me president of our association was entirely unexpected.

While I deeply appreciate the trust conferred in me, I declined my proposed re-election when first discussed on the grounds that

Right to Left—President Robert Cameron, President-elect John Barnet, Past-president William N. Craig, Secretary M. C. Ebel.

I belong to what is known as the young men of the profession, and that there are still many older members available who could most creditably occupy the office tendered to me.

While I do not feel that I shall be able to surpass the records of some of our past presidents, I am resolved to at least try to equal them during my term in office, and I appeal to all the young men as well as the older men of the association to aid me in carrying out my resolution.

As a first step I should like to see an active campaign conducted to increase our membership both among the gardeners and their employers.

As a token of appreciation for what our president has accomplished for the good of our association and the noble profession it represents, let us set the time to begin our campaign now, and let us enlarge our membership before Mr. Cameron retires from office. I am sure he will not be opposed to my suggestion. If you cannot personally reach the fellow gardeners of your acquaintance, who are not yet members, and will send their names to our secretary, he will write to them for you. He will also send you application blanks for those friends you can reach, if you will apply to him for them.

Do not overlook the importance of trying to interest your employers to become sustaining members. Show them the list of our sustaining members which appears in the GARDENERS' CHRONICLE. These members have become an influential part of our association and we want more of them. The secretary will willingly write your employer on the subject; if you prefer him to do so and will so instruct him.

In conclusion, I ask that we all unite to make our association the most influential of all organizations for the advancement of horticulture in America. Let us ask ourselves "What are we doing to help our association?" and not "What good is the association to us?" As its influence for good becomes more generally known, we shall all benefit thereby.

JOHN BARNET, *President elect.*

MEETING OF THE BOSTON BRANCH

The Boston branch of the association held a meeting at Horticultural Hall, September 26, to receive the reports of the convention committees. President Cameron officiated at the well attended meeting. W. N. Craig submitted the financial statement which showed only a very slight deficit on the expenditure of more than \$1,000 for the entertainment of those attending the convention. The stenographic report of the business proceedings of the convention was at the meeting's disposal, and detailed the discussions in which some of the members present had participated.

Mr. Craig stated that many letters had been received from distant visitors to the convention, expressing their appreciation of the welcome and the hospitality extended to them. The beautiful rose gardens, wonderful collection of trees and shrubs, and splendid condition of the velvety lawns were a revelation to those who had not before visited the estates in the vicinity of Boston. The arrangements which facilitated the work throughout the business sessions, regarded as most interesting and instructive, were also commented on, all of which was pleasing news for the members of the various committees to listen to.

NEW MEMBERS

Sustaining Members: Arthur Lyman, Waltham, Mass. (George F. Stewart, superintendent).

Active Members: Charles C. Case, Lake Forest, Ill.; Roy H. Caverly, Lowell, Mass.; Walter Hunt, Somerville, N. J.; C. M. Wagner, Baltimore, Md.; Sidney C. Abraham, Prides Crossing, Mass.; Neil McCallum, Pittsburgh, Pa.; William G. Williamson, Locust Valley, L. I.; John Cotterton, Elberon, N. J.; George Harbison, West Somerville, Mass.; John Costoff, Sharpsburg, Pa.; Joseph Reardon, Cambridge, Mass.; Donald Crighton, Ipswich, Mass.; James E. Bond, South Lancaster, Mass.; Arthur Gates, Purchase, N. Y.; J. D. George, Beverly, Mass.; Thomas J. Murphy, Chestnut Hill, Mass.; Niels G. Erickson, Magnolia, Mass.; W. D. Y.; Edgar Caddick, Wellesley Hills, Mass.; Donald Campbell, New York, N. Y.; Henry T. Raymond, Saxonville, Mass.; William H. Smith, Beverly, Mass.

Associate Members: George Cruikshank, Boston, Mass.; Lindsey B. White, Boston, Mass.; George Strange, Rye, N. Y.; John H. Troy, New Rochelle, N. Y.

REMINISCENCES OF THE GARDENERS' CONVENTION

John H. Troy

Leaving New Rochelle, N. Y., September 12, it rained continually during the six hour trip to Boston. William Munroe of California, a member of our party, said that it was the first rain he had seen in six months, which went to prove that America was not dry. We took a taxicab to the Hotel Brunswick, where we had made reservations, but that did not count as we were informed that the hotel was full, inside and out with gardeners and would-be gardeners. We were sent, however, to the Hotel Buckminster where they had reserved for us a beautiful spacious apartment, which accounted for our not attending the Wednesday morning session of the convention, as Munroe insisted that we ought to stay in the suite of rooms to get our money's worth. That's the Scotch of it.

The annual banquet of Wednesday evening brought the members into more intimate touch; and with that national toastmaster, Charles Hoitt in the chair—who discharged his onerous duties with a wealth of wit, humor and repartee—the banquet was voted a "humdinger."

I would suggest that at our next banquet, the speakers' table be on a raised platform for greater visibility and other possible opportunities; who would not like to have thrown a few shells at Jim Stuart, when he told about oysters not being popular in Scotland, as there was too much waste in them, as the Scots could not eat the shells.

But the scheduled speakers did not have all the glory of entertaining; good stories were the order at all the tables. Down at our end of the banquet room, Wm. Anderson told a good one about two travelling gentlemen in a Boston Hotel who got to talking about races. One said that the closest race that he had ever witnessed was at Saratoga where the two winning horses were running neck to neck and head to head; when going under the wire one horse flapped out his tongue and won by it. The other gentleman said that he had seen a still closer race than that; he was once in Scotland.

Nothing could have been finer or more inspiring than the arranged outings; the first day's outing was a genuine surprise to us New Yorkers; presenting the beautiful estates along the North Shore. This scenic loveliness was topped by an event equally delightful; after viewing the estates, we unhorsed at Castle Hill Farm, the R. T. Crane, Jr., estate at Ipswich over which the president of the N. A. G. is superintendent. There we followed the leader down to the sea shore where we sat down on rugs laid on the sand dunes. After a most sumptuous clam bake some joker proposed a rising vote of thanks to Mr. and Mrs. Crane. It was noticed that only about half of the diners stood up; the other half, too full for utterance, kept their seats on the sand, but managed to say: "hear," "hear" and "bravo";

but Robert Cameron saved the day by marching us up the long hill and by the time the return was made to the cars, we were all fairly back to normal.

How we did revel in the rock garden and arboretum of the Thos. E. Proctor estate. It added to my pleasure that I rode in the same car with that natural born genius of a gardener, James Marlborough.

The second day was equally enjoyable; one well-kept estate after another unfolded before our advancing company; and these continuous beautiful places, together with the scenes of historic interest, the literary shrines, other quaint and distinctive places, the opportunity of viewing advanced horticulture in rare and comprehensive display proved an uninterrupted enjoyment and an invaluable interest. It could not but arouse in me intense convictions that a convention such as this one is a liberal education and an incentive. At such a gathering one meets horticulturists capable in the many phases of their profession, and cannot but go away with added knowledge. To be able to compare practical knowledge with men of their experience and ability, is not only of immense value to the gardener, but to the gardener-employer. I feel that I must make a plea for the gardeners to back up the N. A. G. There is no doubt that it is putting the profession of horticulture on a higher plane. It is a society to be proud of, and the representative men who are lending their efforts and covering the map of U. S. A. with the strengthened and worthwhile purposes of the Association deserve the heartiest support and financial aid of the members.

Another feature of this annual convention is that it is invariably held at attractive places and provides a pleasant vacation where the gardener not only goes with profit to himself professionally, but he can take the women members of his family and give them a charming trip under delightful conditions. The ladies at the convention just passed proved a refreshing part of the company. They were not noticed smoking cigarettes, and they were most attentive and gracious to their own husbands (most remarkable). It would be difficult to find a group of women pleasanter for brightening the social part of a convention assemblage. They were as nice and sweet and womanly as could be; another reason, and a lovely one, for belonging to the N. A. G.

FAMOUS MASSACHUSETTS ESTATES.

(Continued from page 299)

best known garden in Greater Boston. It is a garden, the character of which is entirely different from that of most of the other estates visited, there being no room for great stretches of lawn and for extensive plantings of trees and shrubs. Accordingly much attention has been given to purely ornamental features, including statuary, fountains and the like. Its Italian garden has often been photographed and described. In addition there is a small Japanese garden. Duncan Finlayson, one of the best known gardeners in New England, is in charge of this famous estate.

ESTATE OF E. D. BRANDEGEE

Faulkner Farm in Brookline, the estate of E. D. Brandegee, has been in charge of W. N. Craig, former president of the National Association of Gardeners, for many years. Mr. Craig who is going into landscape work has been succeeded by James Methven. There are 250 acres of Faulkner Farm, much of which is given over to vegetable gardens and farm crops. It contains a great many ornamental trees and shrubs, however, and some rock gardens, in which Mr. Craig has taken much pride. On an elevation adjoining the house there is a large formal garden, the most interesting feature of which is a pool and oval pergola at one end. Here many valuable ornamental features are to be found and the pergola itself is covered with a luxuriant growth of *Aristolochia* and other vines.

ESTATE OF PROF. C. S. SARGENT

Holm Lea, as the estate of Prof. C. S. Sargent, director of the Arnold Arboretum, is called, is in Brookline, but not far from the arboretum. Here a brick house with a strong English suggestion is set close to the ground, and is surrounded by wonderful broad sweeps of lawn bordered by trees and shrubs, including many kinds from foreign lands. This estate has long been famous for its rhododendrons, and in years past has been opened to the public when they were in bloom. Unfortunately many of these were destroyed by the hard Winter a few years ago. Here, too, is a splendid collection of lilacs and ornamental crabapples, together with many Chinese and Japanese trees. This estate also includes greenhouses in charge of Charles Sander, who is little less than a wizard in the handling of rare ornamental plants. Here the Kurume azaleas were brought into flowering for the great show in Boston a few years ago, and here, too, many rare importations are tested out.

The photographic illustrations are through the courtesy of Roderick W. Ross, Dixmont, Pa. Originals of these photos and other photos may be secured from Mr. Ross.

CLEVELAND HORT. SOCIETY

The monthly meeting of the above society was held September 14. President R. P. Brydon in the chair. The flower show committee reported progress.

C. M. Scherer, pathologist of the Davey Tree Expert Co. of Kent, Ohio, was the speaker of the evening, giving an interesting talk on fungus diseases of trees. Mr. Scherer first outlined what fungus is, following with the life history of the chestnut leaf blight, elm tree twig and branch fungus, and fungus which attacks other parts of trees. Spraying with fungicides as a preventative before July 1 was considered by Mr. Scherer as the best treatment for leaf fungus or rust; for other eradication and sterilization of all infected parts, or trees, and planting of species immune from attack of the disease. The birch and hickory tree borer was discussed and the ravages it is making throughout the country with no preventative in sight to help combat the pest. A rising vote of thanks was tendered to Mr. Scherer. William Temblett and Mrs. Ella Grant Wilson spoke of the progress of the society and outlined what may be done in the future.

W. J. BRUCE, *Sec'y.*

NASSAU CO. HORT. SOCIETY

The regular monthly meeting of the above society was held at Glen Cove, L. I., October 11. A hearty vote of thanks was given the managers for the splendid way they handled the dahlia show. John F. Johnston and J. Kelly received the thanks of the society and were congratulated on their excellent exhibits on the second day of the show. A letter of appreciation was sent to Mrs. George D. Pratt for securing Professor Fairchild, who gave a very interesting lecture on October 1. The chrysanthemum show will be held on November 2 and 3 in Pembroke Hall. Joseph Adler and John Forbes will again be in charge. Exhibits for the November meeting will be 3 pink, 3 white, and 3 yellow chrysanthemums, special for assistant gardeners. Table decoration of chrysanthemums, all to be low tables.

ARTHUR COOKE, *Cor. Sec'y.*

WESTCHESTER AND FAIRFIELD HORT. SOCIETY.

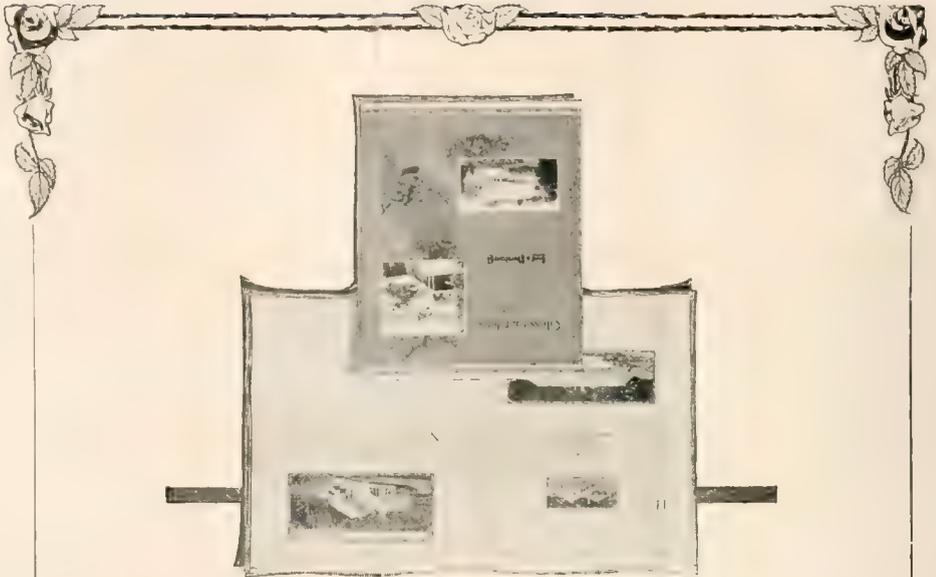

The September meeting of the above society was held in Greenwich, Conn., on September 12.

The exhibits of flowers and vegetables were exceptionally good. Everything was reported in readiness for the annual flower show.

W. Sealy was tendered a rising vote of thanks for the able way in which he conducted the annual outing at Roton Point, Conn., on Aug. 10.

W. W. Gay gave an interesting lecture on Landscape Architecture. A hearty rising vote of thanks was tendered to him.

The annual Dahlia show, held in Greenwich on Sept. 19-20-21, was well attended. There were some large and fine exhibits by commercial men, John Scheepers, Inc., being awarded a gold medal for a fine display of Judge Marcan's Dahlia creations. For the display of Dahlias covering 50 sq. ft. John H. Troy received first prize. Second prize was awarded Mills and Co., a silver medal. Third prize Marnetto Hill Nurseries, bronze medal. Some of the largest prize winners in the private classes were Mrs. W. A. Read, Purchase, N. Y.; Mrs. H. T. Pratt, Glencove, L. I.; Mrs. Dearborn, Rye, N. Y.; Mrs. F. A. Constable, Mamaroneck, N. Y.; Mrs. Whitelaw Reid, Purchase, N. Y.

Superintendents and Gardeners This Specially Interests You

It specially interests you, because it gets right down to brass tacks on the five standard size greenhouses which most of you mostly want.

Each subject is complete in its exterior and interior photos with section, plan and right-to-the-point description.

Although so decidedly practical it is, nevertheless, so beautifully printed and attractive that it will surely appeal to your employers. Here are some of the subjects treated.

1. The Three Bench House 18 feet wide.
2. Four Bench House 25 feet wide.
3. General Purpose Four Bench House Giving You Four Compartments.
4. Plant House and Wings with Four Compartments.
5. The Sectional Construction Its Ease of Enlargement
6. The Construction Fully Described
7. A Rose House 130 Years Old
8. The Most Greenhouse For the Least Money.

Having prepared it all with you particularly in mind, we want to make sure you get a copy. Likewise if you wish, your employer also.

WIZARD TRADE BRAND MARK PULVERIZED

Sheep Manure

Wonderful natural fertilizer for amateur or professional growers—unequaled for lawn, flowers, vegetables, fruits and shrubs—effectively sterilized—no weeds or chemicals—safe and dependable.

Ask your seed or garden supply man for WIZARD BRAND or write direct for full information.

The Pulverized Manure Company
No. 18 Union Stock Yards, Chicago

There were fine displays of fruit and vegetables with competition very keen. The first prize for vegetables was awarded to Mrs. A. J. Moulton of New Rochelle, N. Y. The Garden clubs made a fine showing, all classes being well filled. The amateur classes were also keenly contested. In the class for the best seedling Dahlia William Shaw of Greenwich received a gold medal.

The October meeting was held in Greenwich, Conn., Oct. 10th.

There was a good attendance. The exhibits of flowers, plants, and vegetables was fine, the judges finding it difficult to select the prize winners.

Owing to the illness of the secretary G. Hewitt, John Rutherford officiated in his stead. It is hoped Mr. Hewitt will be with us next month, when it is planned to hold a chrysanthemum show for members.

The members enjoyed an interesting lecture by Henry Bird of Rye, N. Y., entomologist and collector of note, Mr. Bird, illustrated his lecture with specimens and described in detail his big barden, the making of it and the plants to be found growing there.
T. J. BULPITT, *Cor. Sec'y.*

Here and There

SERVICE MEASURES SUCCESS

It isn't the cut of the clothes that you wear
Nor the stuff out of which they are made
Though chosen with taste and fastidious care

And it isn't the price that you paid;
It isn't the size of your pile in the bank,
Nor the number of acres you own,
It isn't a question of prestige or rank,
Nor of sinew, and muscle and bone;
It isn't the servants that come at your call,
It isn't the things you possess,
Whether many, or little—or nothing at all,
It's service that measures success.

It isn't a question of name, or of length
Of an ancestral pedigree,
Nor a question of mental vigor and strength
Nor a question of social degree;
It isn't a question of city or town,
Nor a question of doctrine or creed
It isn't a question of fame or renown,
Nor a question of valorous deed;
But he who makes somebody happy each day
And he who gives heed to distress,
Will find satisfaction the richest of pay,
For it's service that measures success.

—Boys' Life.

GARDEN CLUB OF AMERICA EXHIBIT OF GARDEN PAINTINGS

An exhibition of garden paintings, flower still life and garden sculpture is to be given at the Ferargil Galleries, 607 Fifth avenue, New York City, under the auspices of the Garden Club of America, from November 14 to December 2, 1922. If this meets with success in New York City, it is proposed to send it to some of the larger cities throughout the country where it will have the patronage of the local garden clubs. It is hoped that this exhibition will invite the interest of all garden lovers who are able to visit it.

TO ENLARGE U. S. BOTANIC GARDEN

With a view to enlarging the National Botanic Garden on its present site and to further the scheme for beautification and park development of the area south of the Capitol to the river, Representative John W. Langley of Kentucky when Congress reassembles, will introduce a bill to acquire

about a dozen city blocks. The government already owns much of the land in that section and the adjoining land can be acquired so as to square up the entire tract and make a worthwhile development that will fit with the Fine Arts Commission plans for developing a parkway entirely surrounding the Capitol with a broad central avenue from the river to the Soldiers' Home Grounds.

Prepare Now for the Green Velvety Lawn You'll Want Next Spring

As an ideal winter mulch for lawns, "F. & I."—nature's fertilizer and insecticide—is the logical choice of lawn and garden experts who make careful comparisons.

All winter long "F. & I." will protect your grass from extreme cold and sudden thaws. While the melting snows leach out the potash, ammonia and phosphoric acid which feed the roots in early spring.

"F. & I." is both a fertilizer and an insecticide—a purely vegetable product which rapidly disintegrates, adding valuable humus to the soil. "F. & I." is applied exactly as you would use an animal manure—yet it contains no insect pests or weed seeds and is free from objectionable odor. Many of America's most attractive suburban properties and extensive country estates depend upon "F. & I." for their beauty of lawn and garden.

The F. & I. Tobacco Products Co.

*The Insecticide that
kills plant Lice
of many species*

The Insecticide of Recognized Merit for Greenhouse and Garden

APHINE is a concentrated material—mixes readily in water—efficient in its action—easily applied—free of the disagreeable odors and features of most insecticides—excellent as a wash for decorative plants.

FOR THE GARDEN—As a remedy against all sap sucking insects infesting flowers, fruits and vegetables, APHINE is most effective.

FOR THE GREENHOUSE—Applied at regular intervals (once each week or ten days) APHINE will keep plants in the greenhouse and conservatory free of insect pests.

FUNGINE—For mildew, rust and other blights affecting flowers, fruits and vegetables.

VERMINE—For worms and insects infesting the soil.

Andrew P. Clarkson, superintendent
of the Meyer estate

“I have never seen trees respond so readily”

Tribute of Andrew P. Clarkson to Davey Tree Surgery

The Davey Tree Expert Company, Kansas City, Missouri
Kent, Ohio.
Gentlemen:

I wish to take this means of expressing to you my entire satisfaction with the work performed by your men under my direction on the Meyer estate at Kansas City, Missouri.

In my many years of experience on large estates in Eastern New York it has been my privilege to see a great deal of tree surgery, but I have never seen trees respond to treatment so readily as have those treated by your men here. As evidence of which I am forwarding you several snapshots of your work, showing the remarkable healing over the cement fillings. I shall be glad to recommend your work in connection with the saving and preservation of old trees.

Sincerely yours,

Andrew P. Clarkson, Supt.

Every gardener and estate superintendent has a most important work in the saving of trees under his care.

Davey Tree Surgery brings to his aid the highest development of science plus a generation of experience. A careful examination of your trees will be made by appointment.

LARGEST GROWERS OF PETUNIA SEED ON THE PACIFIC COAST

Petunias—Diener's Ruffled Monsters. Seedlings in 3-inch pots twelve weeks after sowing.

Diener's Ruffled Monster Petunia Seed

The largest and most beautiful Petunias in existence. Have taken first prize wherever exhibited. Plants in 3-inch pots like those above sell at sight as people just want them. The easiest and surest money makers on the market. All seed which we send out is hand-pollinated. Moreover, climatic conditions here permit seed to be matured without a drop of rain falling in the pods. Hence, our seed is strong, vigorous and sure germinating.

Ruffled Monster Petunia Seed comes in the following Colors:

Pink, strong veined center; **Red**; **Variegated**; **White**; **Red**, with black center; **Pale Lilac Pink**, large veined center; **White Giant**, large white of average size; **Mixed**.

Flesh Pink Frilled (Pearl of Kentfield). This and the following varieties are somewhat smaller than the above. One of the most beautiful Petunias ever put out.

Purple or Blue; **White Frilled**, dwarf; **Apple Blossom**, Pink

Seed of any of the above varieties, 50c per pkg.

Diener's Pink Glory

The Greatest Novelty in Petunias for 1922

Pure flame rose-pink without a trace of purple. Flowers measure from three to four inches in diameter. Plants grow to a height of twelve to fifteen inches and are continually covered with flowers. This Petunia has created a great sensation all over the country this season.

Seed, 50c per pkg.

OUR NEW CATALOGUE of Gladioli, Petunias, Amaryllis, etc., will be ready first part of November. It will be free. Send in your name and we will add it to our mailing list.

Delphinium Vanderbilt Hybrids

The best strain of perennial Larkspur in existence. In all colors from light to dark blue mixed. It is mallow resistant and unexcelled for bedding and cut flowers.

Seed, 50c per pkg.

HIGH QUALITY Bulbs · Seeds · Plants FOR AUTUMN PLANTING

This is the title of our Autumn Catalogue which we have been mailing to our patrons during the month of September.

If your name is not on our mailing list, write to us and we will send you a copy of this Catalogue at once.

For the past **twenty-five years** we have been supplying an increasing number of particular flower lovers with our Seeds, Bulbs and many of their garden needs.

HIGH QUALITY BULBS WHY WE USE THE EXPRESSION AND HOW WE ENDEAVOR TO MAINTAIN IT

High Quality Bulbs are bulbs of proper flowering age, grown in a careful manner; thoroughly ripened and cured; and selected for size. The bulbs listed in our Autumn Catalogue are grown in Bermuda, California, Japan, France, but principally in Holland. We contract with growers only for each variety listed. No grower in Holland, for example, grows all the varieties of Dutch bulbs offered by us. Therefore, we place advance contracts for the various varieties with specialists. The bulbs are carefully packed and shipped to us in the autumn.

On their arrival in New York they are immediately unpacked so as to avoid becoming "heated" and carefully arranged in our own building examined and passed on by thoroughly trained men.

Things and Thoughts of the Garden

WILLIAM N. CRAIG

THE question of Winter protection is a most important one, and many gardeners in addition to the great majority of amateur growers have much to learn regarding it. The general idea which seems to persist in the minds of many is that Winter covering is applied to exclude frost and keep plants *warm*. This is wrong in nearly every case. In mulching rhododendrons, the idea is to keep the soil about the roots open, but in the case of hardy herbaceous perennials, bulbs of all kinds, strawberries, and plants which are generally treated as biennials, such as *Myosotis*, *Bellis perennis*, *Campanula medium*, *Digitalis*, bedding violas, and pansies, to mention but a few, if success is to be attained, the Winter mulch is not to go on until the ground is frozen quite hard. If a light coating of oak, or other leaves is then given, and the covering held in position with evergreen boughs or light boards, or a little scattering of loam or old manure over it, the plants should come through in good shape, always providing that they are planted in well drained land where water cannot lay in Winter.

* * *

Stable manure is often used as a Winter mulch; its value for such a purpose is negligent, and with frozen ground the bulk of the manurial agency is washed away instead of penetrating the soil. There can be no better Winter covering than oak leaves, if obtainable, both for plants outdoors and perennials, biennials, bulbs in pots and flats, and the subjects carried over in the cold frames. The failure of many growers to properly winter Canterbury bells, foxgloves, pansies, forget-me-nots, and daisies is usually due to too early and too heavy covering. With the two first named plants it materially assists successful wintering if the outer leaves are cut back severely and a dusting of coal ashes scattered over before the mulch is applied. It is not so much the actual freezing which harms plants outdoors as it is the constant freezing and thawing which lifts plants out of the soil. This is the main reason why mulches are necessary. It never pays to remove Winter covering with the advent of a few premature warm days in March—a suggestion of the tropics is invariably followed by a reminder of the Arctic.

* * *

When the late Fall has been exceptionally dry and there is danger of the ground freezing up before we get soaking rains, it is a very good policy to soak rhododendrons, kalmias, andromedas, and all small leaved evergreens which have been recently planted, for if they go into

the Winter with dry feet and the soil remains frozen for a long time, a heavy death roll is almost certain. The annual "winter killing" of such evergreens as junipers, retinosporas, thujas, and rhododendrons is invariably due not so much to Winter cold as dryness at the root. This is particularly true of new plantings at the bases of houses whose soil is quite porous. Such plantings are usually made distressingly thick with the "immediate effect" in mind, a plan applauded by some landscape architects and nurserymen and which estate owners tolerate as necessary, but which generally gives a jumbled tangle in lieu of some nice individual specimens.

* * *

The necessity of keeping rhododendrons well watered, especially just ere Winter sets in, is not sufficiently realized. If these broad leaved evergreens go into the Winter with moist roots over which a foot of leaves has been spread, they need no further protection, unless it may be a windbreak on the most exposed side. Not in the last twenty years have I given any over-head covering to these plants in New England and even with temperatures as low as twenty to twenty-five degrees below zero, the amount of Winter killing has been almost negligible. On the other hand, I have seen beds which have been carefully covered with evergreen boughs or burlap come through in very bad shape. As soon as the covering is removed, the wind and sun raise havoc with these plants, and if, perchance, a real hot day comes just after uncovering, the foliage will always burn badly. Such varieties as *album elegans*, *roseum elegans*, "Charles Dickens", *Caractacus*, *Everestianum*, "C. S. Sargent," and "Kettledrum," to name only a few of the really reliable hybrids, have lost very few buds by Winter killing within recent years. The lace wing fly I consider a far greater menace to successful rhododendron culture than Winter cold. This insidious pest does not trouble plants growing in the shade, but on rhododendrons, kalmias, and andromedas in full sun, it is very destructive. A couple of thorough sprayings, one just before and the other immediately after flowering will keep it in subjection; using a good nicotine spray containing some soap, which makes it more adhesive, and directing the spray below the leaves, will do the trick.

* * *

The action of the Federal Horticultural Board in allowing free entry to plants of *Rhododendron ponticum*,

Asalea pontica, and *Acer palmatum*, not over three year seedlings without having soil washed from the roots, comes as the first dent in their Chinese wall of plant exclusion. The bulb hearing would seem to indicate that the continued exclusion of such bulbs as *Chionodoxa*, *Galanthas*, *Iris*, *Scilla*, and *Fritillaria* was absolutely indefensible and we may reasonably expect the admission of these and others next season. Growers here admit their inability to successfully reproduce them, so why debar them? Much is made of the fact that quantities of cattleyas and one or two other orchid hybrids are being raised from seed here now and that some of them will flower a few years hence. Is anyone propagating *Phalænopsis*, *Vanda carulea*, various orchids like *variosum Rogersii* and *splendidum*, such dendrobies as *Phalænopsis Schæræulea*, such dendrobies as *Phalænopsis Schæræderiana*, *Wardianum*, *formosum*, *giganteum*, and *Dearei*, and odontoglossums? There seems absolutely no reason in debarring such varieties which to many people are much more beautiful than the gaudy omnipresent cattleyas,

* * * *

Hardy chrysanthemums have been particularly good this Fall in spite of quit severe frosts in October. Some growers seem to have trouble in wintering them successfully. They need land which is very well drained, and in New England are always seen at their best planted in borders with a little slope, and either against the house or very near to it. As plants in the average formal garden, they are useful but have their limitations. I have not found that they carry over well from year to year. Young plants pinched until the end of June give the best service. It is a simple matter to carry over a few stock plants in a cold greenhouse, cold frame, or even a cellar with an earthen floor where the plants can get some light. When cosmos, dahlias, gladioli, asters, and other garden flowers have passed, these chrysanthemums prove especially welcome, and as I write (November 10) some clumps outside my home are covered with bloom. The small pompons stand the greatest amount of cold, the singles and anemones blacken more or less as the temperature falls to twenty-four degrees or lower. The following with me have done remarkably well and should succeed with the average grower; "Doris," the hardiest of all, "Ora," "Normandie," "Seven Oaks," "Lilian Doty," and "Roupe! Beauty." There are many other beauties, superior no doubt to the above named in some respect, but not in hardiness.

* * *

While there is no decline in the popularity of the chrysanthemum as a flower, there is an undeniable falling off in the number of exhibitions devoted to this popular Fall flower, and the attendance is not all that it used to be. On the other hand, Spring flower shows have become increasingly popular and profitable. The days of big specimen plants and blooms of chrysanthemums seem to be numbered at least temporarily. The general public grew tired of them and it is refreshing to note the rapidly increasing interest in and popularity of pompoms, singles, and anemones grown naturally. The greater demand for varieties adaptable to garden culture is also encouraging. There will continue to be a place for big blooms, and a more limited one for specimen trained plants, but with their gradual elimination what can be done to make Fall exhibitions more varied and attractive?

* * *

The great charm of a Spring exhibition lays in the infinite variety of subjects to be seen and the fact that the general public is more or less hungry for them after a long winter. On the other hand, when chrysanthemums

come in reason, many of our trees and shrubs are magnificent with foliage or fruit, lawns remain green and some flowers still linger outdoors. While chrysanthemums will continue to be the great feature at autumnal shows, efforts should be made to bring out their decorative effects in vases, baskets, hampers, and for table and mantel effects. The free use of oak and other foliage helps materially in producing pleasing effects. Apart from chrysanthemums, however, there is much material available. The English race of Winter flowering begonias are magnificent. Plants of "Emily Clibran," "Orange King," and other varieties, four feet in diameter, out-do any specimen chrysanthemums in colorful effect and beauty. The smaller flowered begonia, like *melior*, "Flag of Cincinnati," and "Gloire de Lorraine" are not at their best thus early, neither are cyclamens, but quite presentable batches could very well be staged. Then there are nerines, and what can surpass a group of them in beauty? Orchids in a good variety are in season and the addition of groups and single dishes of seasonable fruits and vegetable helps to round out a well varied and attractive show. It is not too late also to include displays of Autumn sprays and fruits such as cotoneasters, *Cratægus*, viburnums, *Berberis*, roses, and many others still in full beauty, and, of course, cut roses, carnations, and other flowers while not of the same quality as in early Spring, will all help to add interest to such a show.

* * * *

That interest in the culture of hardy roses is surely growing is evidenced by the fact that new rose gardens are continually being developed. Plans are under way to create the greatest rose garden of its kind in America in the Arnold Arboretum to cover about three acres of land and cost some \$300,000, which would include all known hardy species as well as the so-called garden roses. Meantime, a large garden with a rose garden as the central feature is planned for Franklin Park, Boston. Work on this will commence next year and part of the planting will be done. It is estimated that 25,000 roses will be planted in this garden during 1923 and 1924. Income from the Francis Parkman fund will provide the necessary \$150,000 for the work. The making of such gardens should help enormously to develop the hardy rose industry.

* * * *

I have always failed to see what greater risk is incurred in importing hardy roses than the stock they are to be grafted or budded on. The latter, however, is admitted and the former debarred. The wholesale dumping of roses grown in the muck lands of Holland and sold for a mere pittance years ago did much to discourage people from planting garden roses. The Dutch stock proved to be notoriously unreliable and short lived, in marked contrast to the British and Irish roses. Great efforts are being made to produce good, hardy roses here to take the place of the "dangerous" foreign articles and with considerable success. Whether the *Multiflora*, *Japonica* and other stock used will prove as satisfactory in the long run as the *manetti* and seedling brier, time alone will tell. Some growers find that the heaviest plants received are very unsatisfactory and make but feeble growth under the best treatment, the cause for which I have been unable to fathom. There is much need for more careful labelling of field grown American roses. In looking over a large collection this Summer, the purchaser, a keen rose enthusiast, said that not more than half the plants purchased had come true to name. This is most regrettable as well as discouraging. It is a poor advertisement for the party sending out such roses, is a practice still too commonly indulged in, and cannot be too strongly condemned.

Hardy Lilies for the Garden

ARTHUR SMITH

THERE are many garden enthusiasts, both amateur and professional, who make a hobby or speciality of some particular plant genus, it may be roses, dahlias, gladioli, or what not; but so far, I have never heard of a Lily specialist.

The various hardy lilies are certainly not surpassed, or even equalled by any other hardy plant in their unique combination of beauty and graceful magnificence. It is surprising that the majority of people owning gardens know so little about them, excepting those grown in pots under conditions of artificial heat, and they have no conception of the numerous hardy kinds, including twenty or more that are native, by which their gardens may have their floral effects increased during several months of the year, and in the exceptional instances to the contrary, the species have been confined to the old Tiger Lily, with the addition perhaps of the Madonna, *Lilium candidum*.

In a country where there are so many native species of lilies, all of which are beautiful and worth while growing, it is strange that this genus has been so neglected by gardeners, and that the merits of this plant are apparently so little known.

It is true that this genus of flowers has the name of being unsatisfactory from the point of permanency and more or less difficult to grow, yet, if their few requirements are attended to, one need not fear disappointment.

None of the hardy lilies present any insurmountable difficulties in culture, although some are less trouble, establish themselves more readily and produce more immediate effects than others.

Coming as they do from many parts of the Northern Temperate Zone, they are found naturally growing under various soil conditions, and in the case of those which have the character of being difficult to establish in gardens, the nearer we can imitate such conditions the more likely we are to be successful. But when we consider the different habits and habitats of this wonderful genus of plants, it is astonishing how large a number of species there are which are not only hardy in our gardens, but which will thrive under the same conditions provided certain special features are borne in mind.

The question of soil for lilies is an important one, and this is too frequently overlooked. At the same time, while some species succeed best when we create specially ideal soil conditions for them, I know of none which will not give a good account of themselves if they are planted in a soil prepared as it should be for all perennial hardy plants. Unfortunately this thorough preparation is in the average garden, the exception rather than the rule.

While requiring plenty of moisture, thorough drainage is essential and the subsequent cultivation cannot be too deep, nor the soil made too rich. A sandy loam is mechanically the best, with which should be incorporated plenty of old, well-rotted manure, leaf mold and peat, with enough sharp sand to create a suitable mechanical state if the soil is at all heavy.

Probably the greatest mistake made in lily culture is in not planting the bulbs deep enough—a fault which is too often connected with the planting of all hardy bulbs. In most cases there should not be less than eight inches of soil above the top of the bulb, and those with large bulbs like the Japanese kinds should not have less than a foot of soil over them.

All lilies like a cool soil and for this reason generally do better when growing among other plants, and the taller

species are therefore especially at home among such things as Rhododendrons provided the latter have been properly planted and suitably cared for. Other suitable positions are among the dwarfier species of shrubs and in the perennial border among peonies. In these cases the lilies give floral effects at a time when there would be no flowers at all. An exception to planting lilies in the above situations is the well known exotic *Lilium candidum*, a species which stands by itself. This has been under cultivation for many hundreds or perhaps thousands of years, and is native of South Europe and of Asia as far East as Persia. Up to a generation or so ago when any one spoke of lilies in a garden this was the only species meant.

Its uniqueness consists in the fact that a month or so after the flower stems have died down the bulb sends up an Autumn crop of leaves. For this reason the bulbs must be planted sufficiently early in the Autumn to enable these leaves to be produced, otherwise the bulbs will not send up a flower stalk the following season, and in fact will probably rot in the ground. With proper care, however, these may be transplanted both in the Autumn and in the Spring when the leaves are green, by lifting them with a good ball of earth, wrapping the ball in burlap and planting without removing the burlap. This characteristic of throwing up a rosette of leaves both in Autumn and Spring renders it necessary to grow this lily under conditions where it is not shaded by, or in competition with, anything else.

Even under the best conditions *candidum* will rarely give a very good account of itself the first year after planting, and in fact needs several years to accustom itself to new surroundings. When once established and flowering well it should never be disturbed. It is well with this species, and in fact with all, to remove the flower buds before they open the first year after planting, taking care not to injure the stem. *Lilium candidum* is also exceptional in disliking peat, in fact prefers a sweet soil and is not adverse to the soil containing a little lime; it will also do better on a heavier soil than any other species.

While, with the latter exception, all lilies do well when the soil is shaded by other plants, most of them will thrive when grown in groups by themselves; in which case the soil should be mulched after they have started to grow in the Spring.

A characteristic feature of nearly all our *native* lilies is that their bulbs are annual after the same principle as those of gladioli. These annual bulbs are produced at the end of a perennial rhizome, which causes the flower spike to come up in a more or less different place each year. The only native lily which bears an absolutely perennial globose bulb after the manner of the well known bulbs imported from the East is *Lilium columbianum*.

The following list of native lilies, while not complete, comprises those of importance and which can all, we believe, be obtained through growers of native plants.

Lilium bolanderi is a rare species from California, growing from one to three feet tall, with reddish purple flowers spotted with black. Requires a rich, well drained sandy soil. *Canadense* is a beautiful species and perhaps the best known native lily, being found over the entire Eastern half of the country. Its stems are up to five feet tall, carrying drooping flowers of orange, red and yellow, spotted with brown. It likes a deep, rich, moist soil and partial shade, but stands the sun well provided it never suffers for want of moisture. *Carolinianum* is a beautiful

species having recurved orange flowers, very fragrant. Although it is called the Southern Swamp Lily it stands comparatively dry conditions better than any. Found in Virginia and southward. *Catesbaei* is one of the earliest to bloom, March and April, and should have a sheltered position, among dwarf evergreens for instance. It rarely grows more than two feet high and has red flowers with purple spots. In the North it should be thickly mulched during Winter. *Columbianum* is a rather uncommon species from Oregon and Washington. Height two to three feet: flowers bright orange with purple dots. This has been found a good species for the hardy border. *Grayi* is one of the best and has succeeded well under cultivation. Flowers are bell-shaped and exceedingly beautiful, dark reddish-brown spotted with purple, borne in July and August; height two to three feet. All perennial borders should have groups of this. Found on mountain summits of North Carolina. *Humboldtii* (*puberulum*), is a Californian species very deserving of more extended cultivation. It reaches noble proportions, sometimes as tall as eight feet, and bears large orange-red flowers spotted with purple, six to ten on a stem. *Kelloggi* while smaller than the preceding is very graceful, its slender stems three to four feet tall bearing as many as fifteen pink flowers which are very fragrant. *Maritimum* is a dwarf species from boggy situations on the Californian mountains and is an excellent subject for the Bog Garden or along the edges of water just above its level. *Philadelphicum*. This species is found, generally in woods, over a large part of North America extending from Canada to North Carolina and westward to the Rockies. While in its natural state it selects somewhat shady situations, it will stand sunny, dry ground better than perhaps any other and it will grow almost anywhere excepting in a wet soil. It is a good species for planting along woodland walks and amongst shrubs. *Superbum*. It would be rather difficult to exaggerate the superb qualities of this magnificent American Lily. One has to see the seven foot tall, leafy stalk, surrounded by a cluster of from thirty to fifty brilliantly beautiful orange and gold flowers, before they can realize the impressiveness of this species at its best. While it is native of somewhat swampy places in the Eastern half of the country, it will do well in borders provided it has a deep, rich soil containing plenty of peat and leaf mold, and never wants for water. It is one of the best Lilies for the Rhododendron bed. It is found from New Brunswick to Georgia. *Washingtonianum* is a Californian species and when it does well is a beautiful and stately lily, but it is rather capricious in the East, although many have found it to be an excellent garden kind. Its flowers are white with purple spots and the entire blossom becomes tinged with purple after fully expanded. This lily will not endure stagnant water. A variety of this, although by some considered a distinct species, is *rubescens*, having more striking characters and it is said to have been found growing to a height of twelve feet.

As, with the exception mentioned, the bulbs of these native Lilies are small, annual, and are borne upon rhizomes; they are both very tender and must be handled with great care, the numerous, fleshy scales of the bulbs being very easily detached. Doubtless it is this tenderness which has been the cause of many failures in bringing these lilies into cultivation, and unless extreme gentleness is used from the moment of lifting them from their growing position until they are planted, more or less damage is sure to result, and if the bulbs live they may take several years to recover. Another point is that these bulbs should not remain out of the ground a moment longer than necessary, and when sent to a distance more care in packing should be exercised than is usually the case.

In addition to the native lilies, of which the above list contains the names of the better half, there are quite a few exotic species which should be planted for the purpose of making our gardens more beautiful. Some of these have the discredit of dying out in a year or two, but in the main, this failing is generally caused by bad soil and want of care.

Undoubtedly the first lily to be brought into cultivation was *Tigrinum*, and it should still be grown as much as ever. The old, original kind is handsome but the newer variety, *splendens*, has grander, orange-red flowers, grows six to eight feet tall and blooms a month or two later. There is also a double flowered variety which is the only double lily known. This species can be propagated by planting the bulblets which form at the axils of the leaves, in fact it spreads naturally by means of them and is now found wild in several Northeastern States. *Candidum* has already been mentioned. *Croceum* is in common cultivation in Europe of which it is a native, and it is one of the sturdiest and hardiest of the genus. It will grow in almost any soil or position and bears in Summer huge heads of large, rich orange flowers. It is attractive in the mixed border but shows best on the margin of a shrubbery where its stems just over-top the surrounding foliage. It is native of the colder mountains of Europe and naturalizes well. Some of us can perhaps remember the stir made by the arrival of the Golden-rayed Lily of Japan, *L. auratum*. A small consignment was sent, said to be bulbs of a very large Lily growing wild upon the Japanese Islands for which fabulous prices were charged, but of those who paid big money for these bulbs only a few obtained any results, and practically the first consignment was a failure. The gorgeousness of the comparatively few flowers obtained, however, caused the next consignment to sell very freely, and with more knowledge and experience in handling, and growing them, this lily soon rose to a foremost position among garden plants, especially in Britain. A striking point about *auratum* is its variability. If you plant a hundred bulbs not more than half a dozen will be alike either in flower or height of stem, even if the planting is confined to a named variety, of which there are several. The best is *platyphyllum* distinguishable by its palmate leaves, the leaves of other kinds being more or less linear. It has been also proved to have the hardiest constitution. Unfortunately under the conditions prevailing it is practically impossible to obtain any varieties reliably true to name through ordinary trade channels.

This Lily requires a deep well-drained soil composed of peat, leaf mold and sandy loam, equal parts of each. It is susceptible to cutting winds and should have a nook sheltered by shrubs or something from north and east winds. It has proved itself very permanent among Rhododendrons when the latter have been properly planted, and the yearly mulching with leaves is also of great benefit, as it is to all Lilies. When grown in the open border a mulch of rotten manure after the shoots have started should always be given. Under ordinary conditions in a garden where plants look after themselves this lily deteriorates and dies out sooner than any, but in a suitable soil combined with proper attention it will increase and give a good account of itself year after year. Another Japanese species is *speciosum* which has several varieties. While not so gorgeous as *auratum* it is certainly as beautiful and in North America has proved itself to be permanent under soil and other conditions advised for *auratum*. The best, hardiest, and most permanent of all exotic lilies is undoubtedly *regale* from West China. It has rich, green foliage with which the exquisite color tints of the flowers form a charming contrast. It has the advantage of being easily propagated from seed, seedlings generally

blooming the second year. A distinct advantage is connected with *regale* inasmuch as it is propagated in this country, therefore bulbs may be obtained direct from the growers at the right time for planting without being subjected to the deteriorating effects of having to remain a long time out of the ground, which weakens more or less both their growing and lasting qualities.

While there are other lilies worth growing out of doors, it does not appear that any practical purpose will be served by further extending the list, although a complete collection of them would afford an extremely interesting and unique feature in a garden. At all events Lilies should certainly form a more prominent characteristic of our hardy flower gardens than is at present the case. We know that the general complaint about them is that they soon die out. But this is not an inherent fault of the lilies.

Even if the soil and other conditions are right, lilies, or for that matter any other bulbous plant, will not be permanent unless they are allowed to die down naturally. Seed pods should be removed, unless seed is required for propagating, and they all can be raised from seed, although some take as many as eight years to reach a flowering stage. Some growers advise that the first year after planting all flower buds should be removed as soon as formed, taking care not to injure the stem. Naturally when they are planted in hard ground and receive no care, lilies will not do much and will soon cease to exist. But there is no hardy plant which will more fully respond to proper treatment or that will add a more pleasing note of beauty to our gardens during many months than the Lily.

Lilies should have a mulch after the first hard frost of about six inches of leaves, these leaves should be allowed to remain all Summer and another similar mulching given at the beginning of every Winter. For cut flower purposes more or less of the stems must be removed, but as much should be left as possible. Growing lilies in narrow beds renders it easy to erect a lath shade over them and so increase and prolong their beauty.

The best time to plant Lilies is as early in the Autumn as possible; where imported bulbs have to be used and which do not arrive until late their position should be covered with some kind of material to prevent the ground from freezing, so that planting can be done as soon as they arrive.

In conclusion we emphasize the necessity of deep planting in a deep, light, rich soil, which must never dry out.

WINTER VEGETABLES AND SALADS

KALE can be kept in a vegetable garden the entire year, excepting when the mercury drops below zero. Its flavor is very much improved by exposure to frost. Slight protection is all that is needed to keep it in usable condition. Simply mulch the Summer-grown plants with leaves, dry grass, straw, or any other suitable covering.

The dwarf varieties are specially deserving of prolonged usefulness. The leaves are a rich brilliant green color, bordered deeply with curled fringe and are attractive for garnishing. Its chief value, however, is as a vegetable similar to spinach.

Any surplus growth of brussels sprouts in the home vegetable garden can be retained fresh and green for indefinite Winter use. The whole stocks with roots attached should be taken from their place of growth and piled together somewhere in the garden and covered thickly with straw. They will freeze solid in cold weather, but the freezing process, instead of rendering them useless as it does most vegetables, conserves the original color, flavor and edibility. The frozen sprouts

should not be allowed to thaw, but should be put at once into boiling water to cook until tender.

Crisp green salad and deliciously tender rhubarb may be had all Winter long from a cellar garden.

To accomplish this have installed in the furnace room or cellar, the temperature of which must average 60 to 65 degrees, a box or built-in container for soil. A good average size is 6 feet in length, 3 in width and one in depth. Fill it in with 7 or 8 inches of garden soil and in November secure from the garden the Summer-grown roots of witloof, chicory and rhubarb—or they may be secured from any reliable seed house or, in some cases, from a local gardener. Cut off all the leaves two inches from the necks of the plants of both chicory and rhubarb, and remove any secondary shoots from the chicory. Make trenches in the soil and set the plants 2 inches apart, water them thoroughly and cover them with soil until the box is level full. The weight of the soil will assist the leaves of the witloof to grow incurved and together, forming small, well-blanching heads like Cos lettuce.

If a few salads are wanted for early use cover the chicory plants heavily with manure, which will raise the temperature below and hasten growth. Those not so covered will be correspondingly later, so that a succession may be enjoyed. The rhubarb too, will grow through the soil finely blanched and delicately tender.

Still another way to produce successional cuttings is to store some of the roots in a cool place where they will remain dormant, and plant a few at intervals. It requires three or four weeks to produce the heads of witloof in a temperature of 60 degrees. Too much warmth should be avoided as a spindling growth results.

When cutting chicory for use, remove the plants and cut off the heads leaving an inch or two of root attached to prevent the leaves from falling apart. All roots should be removed from the soil to insure its keeping sweet for successive plantings. Cut them just before you are ready to use them, as the leaves quickly turn green when exposed to the light. The rhubarb may be removed and used in the same way as if taken from the Summer garden.—*The Christian Science Monitor*.

Let us have faith that right makes might, and, in that faith, let us to the end dare to do our duty as we understand it.—Abraham Lincoln.

The Garden of Annuals and Perennials of Andrew Wilson, Springfield, N. J., Which Furnishes Him a Wealth of Blooms Until Frost. A Rose Garden Is in the Background

Roses in the Fall

IT is a growing conviction with the writer that any Tea or Hybrid Tea which has bloomed freely during a single season has "squared itself" with the owner for its purchase price. If it endures the Winter and again goes about its work of beauty another year, the rose-grower owes it at least care and gratitude, or a successor should Winter claim it.

The first expression of this care ought to be in proper preparation for the Winter. Some parts of this preparation are here suggested.

1. *Do Not Stimulate Late Growth.* The Tea and Hybrid Tea roses tend in Fall to renew active growth, and many fine buds are produced in the weeks before frost. To withhold fertilizing and extra water in these weeks helps to ripen the wood for better endurance of the Winter.

2. *Clean Ground and Clean Bushes.* Not a weed should be permitted to compete with the rose plant for soil fertility. Now, in Fall, as at no other time, it is especially important to have the bushes and the ground clear of dead and diseased leaves and twigs. If "black-spot" has been with you, every vestige of its ravages, either yet on the plants or in fallen leaves on the ground, should be removed and burned. Make sure that Jack Frost has only healthy leaves to cut off, and that he doesn't simply store for you unharmed next year's black-spot infection.

A heavy dusting of the plants and the ground with the sulphur-arsenate powder (9 parts dusting sulphur, 1 part lead arsenate) will be worth while, especially as it now appears that where this has been done for several seasons the nasty rose-bug seems to be diminishing his vigor. Mildew is also guarded against by this treatment.

3. *Fall Pruning.* The longer canes of the Hybrid Tea roses ought either to be cut off—say above two or three feet—or tied in, so that wind whippings may not loosen roots. Of course, the final pruning must be delayed until Spring.

Hybrid Perpetuals can be tied down after the longest tips are cut away. Rugosas need no protection.

Hardy climbers should also be made snug by preliminary trimming, or better by tying down. In these roses, as in Hybrid Perpetuals, the next year's bloom shoots arise from this year's wood, wherefore severe pruning is wrong.

4. *Labeling.* All roses ought to be so labeled that there is no doubt of the variety. Whatever label is used, it is important to properly consider its security in putting the roses to bed for the Winter.

5. *Protection against Frost.* Only hints may here be given, because of the wide range of climate the American Rose Society covers. Any rose is "hardy" anywhere if adequately protected.

Usually, wind and the sun do more harm than temperature. The wind vastly increases evaporation and temperature effect, and even Winter sun may stimulate unwary buds to swelling, only to be bitten later with the frost.

So protection should be against wind and sun. To hill up ground six to twelve inches around the smaller bushes is a good protection. To thickly cover the bushes with evergreen boughs is excellent, and usually sufficient save in the coldest regions. If field-mice do not abound, leaves are good protection, provided they are so covered as to keep them measurably dry, for sodden leaves, or sodden manure, may rot rose stems. Protection need not be applied until the ground is lightly frozen.

Heavy paper can be so used as to keep off wind and sun, and the straw jackets once considered essential are usually safe.

In very severe climates much more elaborate protection must be worked out, and, of this, information should be sought in the immediate neighborhood by looking up the nearest associates whose names are to be found in the geographical list of members in this Handbook.

6. *Planting Roses in the Fall.* Many of the best rosarians insist on Fall planting, having discovered that the roses will thus be prepared for an early start. Plants can usually be obtained in fine condition after the first frosts, and if the ground is carefully prepared and the roses carefully planted, a further covering of soil will afford protection. Fall planting has much to commend it.

But if for any reason Fall planting is not practicable, we commend Fall purchase of the roses. Get them to your garden, and bury the bundles of them (divested of wrapping, of course) completely under a foot of soil, marking the place for convenience, and again covering the soil with any litter to prevent the severest freezing. Such "heeling-in" must of course be where water cannot stand—no rose will endure wet feet.

This Fall buying and home storing is the solution of many rose troubles, provided the purchaser also prepares his next season's beds so that he can put the bushes where they are to bloom at the earliest possible date when the soil can be worked in the Spring.

Roses make root growth very early, and it is far better to have that growth made in your garden than in the nurseryman's rose-cellar. Planting a week or two earlier in Spring may mean the gain of a whole season in rose prosperity, and not infrequently means the saving of the plants.

Fall purchase and home storage secure not only the earliest planting opportunity, but the first and best choice of the freshest plants from the grower.

Getting Ready for 1923. Great advantage follows the preparation of the ground in the Fall, so that the beds are ready in earliest Spring. The soil settles, the manure breaks down, the sods decay, and the whole mass improves over Winter, providing the best planting conditions for Spring.

No longer is the elaborately deep soil preparation considered essential. From eighteen inches to two feet of good soil, including well toward one-third its bulk of thoroughly rotted stable manure, if cow manure is not available, and with a basis of bone-meal equal to a trowelful for each rose, will provide good feeding-ground for roses. If the soil is heavy and the drainage poor, deeper digging and heavy and rough material at the bottom are required.—J. Horace McFarland, Editor of Publications of American Rose Society, in *Members' Handbook*.

CLIMBING PLANTS

All climbing plants are vigorous growers, and unless dealt with at once soon become a tangled and uninteresting mass, almost impossible to separate. When tying of any description is done care should be taken to tie slightly, allowing the subject a fair amount of freedom in order to maintain a loose and natural effect. Once the fence, pergola or whatever the various subjects are intended to clothe is furnished allow the plants more freedom, and pretty effects will accrue. Clematises, Pyrus, Roses, etc., are often deprived of their natural beauty by the stiff training they receive.—G.

Bulbs of Easy Culture

PERHAPS the simplest bulb to handle is the paper-white narcissus. It is one of the earliest varieties of the narcissi group but can be had in bloom for a long time by successive plantings at intervals of about a week. As for the medium in which to grow the bulbs, there is nothing simpler and cleaner than a shallow bowl of water containing pebbles to support the bulbs in an upright position. In planting, a layer of pebbles is placed in the bowl, the bulbs set on this layer, and some pebbles packed about each one to hold it in place. The water

Paper-White Narcissus

should come barely to or a little above the base of the bulbs. With a large bowl it is recommended to change the water occasionally, but with a shallow one this is almost impossible without disturbing the pebbles and injuring the roots. If a few pieces of charcoal are placed in the bowl the water will be kept fresh, so that it will never have to be changed but only enough added to allow for evaporation. If any bulb should rot and thereby contaminate the water the affected bulb should be removed and the water changed, but this seldom occurs with narcissi unless the bulbs have been injured before planting.

The bowls containing the bulbs should be put in a cool dark place, a fruit cellar being an ideal location. The essential points to remember at this stage of the bulb growing are (1) that the storage place be kept dark to prevent the leaves from starting; (2) that it be kept cool, the roots then being able to grow before the tops; and (3) that the bulbs get plenty of air. In selecting a cool place a temperature of from fifty to sixty degrees will suffice, but it is better if it can be still cooler. Temperatures below freezing must be avoided. Sometimes a cool dark place is not available, and in that event a corner in a comparatively cool room can be darkened with a box and the bulbs placed in this. If the room is very cool

root growth will not be as rapid as in a warmer room, but when the bowl is well filled with roots it can be brought to the light. The leaves will then have started and may be a few inches long and white, and on that account the bulbs should be brought to the light gradually. After growth is well advanced they may be placed in a sunny window for a short time each day. Bulbs that are started in a cool place will produce a sturdy growth and the flowers will last longer than those that have grown rapidly in a very warm room. Narcissi treated in this manner can be had in flower from six to eight weeks from the time of planting.

Paper-white narcissi can also be grown in soil in pots under similar conditions. If a cool dark place is not available for storing the bulbs indoors a shallow trench may be dug in a well-drained place outdoors. In this trench from two to three inches of ashes should be placed for drainage, and on this the pots set so that the rims are about six inches below the surface of the soil. The trench should then be filled with soil and the surface mounded to shed water. As the weather becomes colder the soil should be covered with leaves or some other coarse material, this being held in place with boards. Four weeks is the shortest time the narcissi should be left outdoors,

Roman Hyacinth

six or eight weeks being better. The bulbs should be planted in pots or pans, preferably the latter. A good quantity of broken crocks or stones should be placed in the pots for drainage, then a layer of good garden soil, and on this the bulbs set so that when the pot is filled with soil the necks of the bulbs will be barely visible. They should then be watered thoroughly and put in the storage place.

The Chinese sacred lily can be grown in bowls of water and pebbles, but not as successfully as the paper-white

narcissus. The bulbs are much larger, deteriorate rapidly in the dry atmosphere of the stores, and cost considerably more than the paper-whites. It is therefore advisable for those who have never grown bulbs indoors to first try the narcissi and as cultural experience increases attempt growing the Chinese sacred lily.

The Dutch hyacinth is also readily grown in water, but it takes longer for the flower to develop and only one bulb may be grown in a glass. (Hyacinth glasses can be obtained at the seed stores.) Only the choicest bulbs should be purchased and preferably named varieties. A piece of charcoal about an inch square should be placed in the glass to keep the water fresh, the bulb set in the cupped portion, and water added until it barely touches the base of the bulb. No pebbles are necessary, but water should be added occasionally to keep the level constant. The bulbs are then placed in a cool dark place, as with the narcissi, and should be left there until the glass is well filled with roots. The plants should never be placed in direct sunlight but brought to the light gradually. The hyacinth has the misfortune of being overanxious to grow, and occasionally the flowers develop so rapidly that the spike cannot get out of the bulb, or sometimes the leaves have grown so fast that when the flowers open the spike is down among them. The Dutch hyacinths may also be grown in pots of soil, in which case they are given practically the same treatment as the narcissi, care being taken that in planting the tips of the bulbs protrude just above the surface.

The Roman hyacinths are bulbs of the easiest culture, and success with them in pots of soil is more uniform than with the Dutch hyacinths. The bulbs are small, but many spikes of flowers come from each bulb. The flowers are loosely arranged along the spikes, giving a more graceful effect than the stiff Dutch hyacinth. They should be given the same treatment as other bulbs, but may be brought indoors sooner than the Dutch hyacinths.

Tulips and other bulbs may be grown indoors, but results are not as satisfactory as with those described.—*Missouri Botanical Garden Bulletin.*

WINTER PROTECTION FOR SMALL FRUIT PLANTS

SMALL fruits should not be permitted to enter the Winter unattended. This class of food producers is grown in practically every garden and still little attention is given the plants. Strawberries, raspberries, gooseberries, blackberries and currants are for the most part a hardy lot. They will grow and bear fairly well with a minimum of attention. It is probably for this reason that the plants are neglected to such an extent. Their thriftiness, however, says the *Stanford Advocate*, should not cause any gardener to neglect the plants. Good growth and fair crops of fruit are not the points to consider in small fruit culture. It is bumper crops and healthy, sturdy plants that should be desired.

Before cold weather closes in there is considerable work that should be attended to. The more carefully this is done the larger will be the production of the plants. Those plantings overrun with weeds need cleaning of them. With the brambles and bush fruits growing in relatively large areas it is best to plow out the central space between the plants, turning the furrows away from the rows. Then, with a grub or other hand tool cut out the grass and weed growth so as to free the rows of noxious plants and leave no harbor for the mice. Before the ground freezes up for the Winter the furrows must be turned back toward the plants again. All sucker shoots coming up between the plants in the rows should

be cut away unless some of the stronger of these are wanted for Spring planting.

In the case of strawberries such grubbing is impossible, but a hand hoe should be used to cut any grass or weeds that may be in the rows between the plants. Many culturists leave their strawberries unheeded until Spring, but this should never be done when there is time for the work in Fall. Plantations left for Spring clearing are usually neglected for other work and the crop becomes greatly reduced as a consequence. In Fall hoeing be careful not to cover the hearts with soil or unduly disturb the plants. If the bed is comparatively free of weeds then this hoeing can be left undone. Some plant food should be given the plants in the Fall and a protecting material applied soon after the ground freezes.

While properly pruned brambles may stand alone through even the most inclement weather, the plants are better off if given support. By erecting supports in the form of stakes or trellises it is an easy matter to tie the canes to them and prevent their breaking or becoming misshapen from the loads of snow and the sleet. While this supporting is not always practical in the commercial planting, it is entirely so in the home garden and should not be neglected. The supports need not be expensive or ornamental. A single wire or two stretched along the row will suffice admirably. The wire should be placed so as to give the plants the maximum support.

Many of the small fruits need Winter protection. Currants and gooseberries are ironclad and need no top cover. Blackberries of most varieties are very hardy. But the raspberries of many sorts are better for a covering at the tops. When this is done the plants can be bundled up, that is, several canes tied to a single stake or at one point on the trellis and covered over with straw, salt hay, cornstalks or other protecting material. Sometimes the canes are turned down to the ground and there covered until Spring with litter and soil. When the more tender brambles can be protected in an upright position it is not advisable to turn them down to the ground.

All the small fruits need mulching at the roots. This stops the alternate freezing and thawing which frequently produces such disastrous results. If the mulch is of manure then the plants are fed at the same time they are protected. The manure should not be worked into the soil, but left on the surface. Broadcast it for a distance of several feet on all sides of the plants instead of immediately surrounding the main stems. Long strawy manure, or that which is half rotted, is preferable to well rotted manure for mulching the small fruits.

In mulching strawberries be careful not to apply too much material over the crowns of the plants. A covering two inches deep of fairly light, loose material is better than a thick mulch, for too thick a protection may smother out or devitalize the plants. Between the rows, the manure or other material may be applied several inches thick without harm.

Only a short time remains to put the small fruits into condition for Winter. While the mulch about the roots may be applied at any time after the ground has frozen the other work should be done now. The sooner it is attended to the better. Next season's small fruit production is dependent quite as much on the Fall care of the plants as on the Spring and early Summer operations.

Work for some good, be it ever so slowly;

Cherish some flower, be it ever so lowly;

Labor! all labor is noble and holy;

Let thy great deed be thy prayer to thy God.

Frances S. Osgood.

Work for the Month in the Garden

SAMUEL GOLDING

Within the solemn woods of Ash deep crimsoned,
And silver beech, and maple yellow leaved,
Where Autumn, like a faint old man
Sits down by the wayside a-weary.

Longfellow.

THE Autumn is drawing rapidly to a close. There are indications on every side that the garden will soon be in the grip of Winter and we have already experienced a foretaste of its icy hand, which has robbed the borders of flowers. The trees and shrubs, which have vied with each other in their gorgeous and exquisite coloring of foliage and berry, have now lost their brightness and are prepared for their Winter's rest.

It remains to us to gather in the remaining crops and to give the more tender plants adequate protection, so that we can look forward with perfect assurance to welcome them again next Spring. All root crops must be brought in without delay. The celery which is now our most important crop, should be lifted and stored away into its Winter quarters before very severe weather sets in. It can, however, be wintered outside, providing it is given adequate protection, which can be afforded by being well earthed or banked up with soil; then covered with other protective material as conditions demand, dry leaves, salt hay, and corn stalks are good, with some boards placed over them in such a position as will throw the water off. They can be lifted and placed close together in one trench, for more convenience in handling, but when left in their growing position undisturbed until wanted for use they retain that desirable nutty flavor, and are crisp and firm to a marked degree.

Cabbage can be placed in a trench upside down or in a conical heap, and covered with dry leaves and straw to prevent frost or water reaching them. They will keep when treated in this manner for quite a long period.

Lift seakale, chicory, rhubarb, and place in a cool place where it can be taken out conveniently for forcing in successive batches during the Winter. They come away more freely when brought into heat, after being exposed to some frost. Take in some horseradish and lay in soil to be on hand when wanted for use during the Winter months.

Beets, carrots, turnips, should be packed away in sand to prevent shrivelling. Lift enough parsnip and salsify to carry over until Spring. These vegetables are improved by being left in the ground, and if enough covering is placed on the land to prevent the ground becoming too frozen, they can be taken up when wanted for use.

Onions should be cleaned and spread out thinly, or tied in ropes by their tops, and hung in a convenient place in a frost-proof shed. It is an excellent way to winter them.

Gather a supply of protecting material to cover the strawberries. Some judgment must be exercised when to apply this protection. No date can be set, but one must be guided by the climatic conditions prevailing. It is best to apply this after the ground has frozen up. Rough litter, leaves and cornstalks can be used.

Protect globe artichokes early. Place some brush over them and cover with rough litter. Keep plenty of salt hay over the endive that remains outside.

Pay constant attention to crops growing in pits and frames; give abundance of air whenever the conditions are

favorable, water very carefully, and remove all decayed foliage. Cauliflowers that were lifted and placed in the frames last month will now be turning in, and will make a welcome addition to the now short list of vegetables.

The mushroom beds will now be in full bearing. When they show signs of exhaustion they can be watered with tepid water in which a handful of salt has been dissolved. Collect more material to replenish the beds, as they cease to be profitable.

Plant deciduous trees and shrubs while the weather remains open. Lift any gladioli, montbretias, cannas or dahlias that may have been overlooked. Store away in a cool place. Some people find montbretias somewhat difficult to keep right through the Winter. If any failure has been experienced when lifted in the Fall, try leaving them in the ground, and use a heavy mulch of leaves. These are flowering bulbs that are deservedly growing in popular favor.

Any herbaceous plants that are prone to die off during the Winter should be lifted and placed in a cold frame. The tritonias and border chrysanthemums are as a rule better off when placed under this protection. There are many other things which come through some Winters quite well and die off during apparently mild conditions or when snow is light. Place canterbury bells, *Myosotis*, *Bellis*, pansies in the frames before very severe weather is here.

Cut over the herbaceous borders. Rake, clean up and burn all leaves and rubbish and throw the ashes on the garden as it is a good fertilizer. Collect all stakes and supports and store away for future. Make preparations for the protection of the more tender subjects. Arrange windbreaks around rhododendron beds, box bushes, etc., in case of a sudden visitation of severe weather.

Cut back the long growths of the roses, which prevents injury from heavy winds. Draw up soil around the base of the teas and hybrid teas, and in exposed places set wire netting around the beds. Cover the ground with leaves when the ground has become frozen.

During the month of December the work in the garden mainly consists of preparation for next year's work, and seeing to it that the plants have ample protection to carry them safely through the long resting period on which they have entered. If material was gathered during the mild days that have passed, it will be on hand in case of a sudden emergency. It is a mistake to cover or give protection to many of the fairly hardy plants too soon, but when we get into December severe wintry weather must be looked for and guarded against. Many hardy plants will suffer if covered by a wet heavy manure, especially so if their foliage persist above ground. When protecting these plants use dry leaves, salt hay, or rough litter, and cover over with brush to keep in position in such a manner that the air can penetrate.

Throw up plenty of soil around the base of the roses. In some districts it pays to lift and bury the plants and transplant again in the Spring; this is always the safest way to treat the standards. If the laying in is not practiced a covering of dry leaves helps to bring them safely through, although the mice sometimes take up their abode there and may badly bark the plants. When the soil is

(Continued on page 318)

The Greenhouse, Month to Month

GEORGE F. STEWART

WE have now come to a season of the year when the greenhouse will give more enjoyment to the owners in the way of cut flowers and plants than during the Summer months. I am well aware that outdoor trees and other plants have a charm all their own, even in Winter, to the artistic and observant mind, yet for brilliant and rich color in this part of the world we have to come to the greenhouse in Winter. When chill November's surly blast blows field and forest bare, it feels good to get out of the chill a few minutes occasionally, and see some of the flora of another part of the world, and I believe that was primarily the idea of glass structures.

I have very little patience with some of our friends, who lately are inclined to have a fling at the greenhouse as a thing of no interest. Indoor and outdoor gardening both have their place, and I think he is a very one-sided gardener who has not a good knowledge of both. I am very thankful that all the gardeners I worked under, as a young man, urged me strongly to be well posted in all matters pertaining to an estate, and a few of them, should I mention their names, had a national reputation on both sides of the Atlantic as all 'round gardeners. Some of us know how hard it is to get a well posted young man for greenhouse work nowadays and I hope that the course in our colleges to train young men as gardeners will in the course of time produce results in that line.

Late November and early December will find the chrysanthemum season about over, except for a few late varieties. We now will have our minds made up as to what varieties we will stick to for another season. Stock plants of these should be cut down to about three inches above the soil. We find, if one has no room in the coolest greenhouse, they can be stored very well in a cold frame, which can be made frost proof by lining the sides with leaves and using mats and shutters over the glass. In a frame with no heat in it, advantage must be taken of all the light and air possible being admitted into the frame; and dustings of air slaked lime, powdered charcoal, and occasionally a little flowers of sulphur given the plants. Keep them on the dry side until the young growths break through the soil. Fumigate the frame at intervals of nine or ten days with tobacco in some of its forms that are common on the market. So far we have found Hall's "Nicotine Fumigator" (powder) the handiest and best. Cuttings of the varieties which we mentioned in a previous article, as being put in about August first, begin flowering about Thanksgiving and continue until after Christmas. They are about a foot high, and as stated in said article, are grown twelve cuttings to an eight-inch pan. We find these about as useful as any chrysanthemum grown the whole season.

Camellias are now loaded with flower buds and if large flowers are desired, thin them out to one bud. Some of the early varieties are flowering with us. We have a plant which has been in the Lyman family for about one hundred years, a cream-colored one; I do not know the name of it. This plant commences flowering early in October, and is the first to flower with us, an excellent variety, but somewhat delicate at the roots. I believe it would do better grafted on a strong grower. The old *Camellia alba*, which in my opinion is the finest

variety of all the Camellias, also begins flowering with us the end of October. Forty degrees at night during Winter in my experience suits them best. They, however, may be grown as high as fifty degrees if required to flower early. This is the best time to pot camellias, if they need a larger receptacle, but they should never be overpotted; they never in my experience do as well as when confined to a small pot and fed with stimulants. I hear a great many complaints about camellias being in a sickly condition and invariably it is due to overpotting and careless watering. The reason that I advocate potting camellias at this season when they apparently have completed growth, is that I find the roots begin to be very active long before any sign appears of growth on the plant. As a rule I have found that while flowering the young roots are starting all round the ball, and being easily broken, it is better to have them potted just as soon as growth is completed. Camellias grow well in either peat or loam. They flower better when grown in loam, but peat gives a better lustre to the foliage. Weak rooting varieties do better in peat. The loam or peat must be fibrous, as if it is in a fire condition it will soon become sour and useless. The poorest plantsmen I ever worked under were great advocates of putting all potting material through a fine sieve. When potting a plant the compost should be as rough as can be conveniently worked around the ball without leaving air spaces. The more fibre in the potting material the better. Use about a third of good sharp sand in the compost for camellias, and a good sprinkling of broken up charcoal. Be sure there is no lime in the soil, as I have found that these plants have no use for it. Pot the plants quite firmly, as solid as the ball of the plant, for if this is not done the water will pass too freely through the new compost leaving the old ball dry. Water the plants carefully and never allow them to get into a wet, soggy condition. Camellias are subject to all kinds of insect pests, but we find they are easily kept clean by using Hydrocyanic gas one half ounce to the thousand cubic feet. There is a black smut that also collects on the leaves sometimes, and, of course, the only way to clean it off is by sponging.

If good, strong, large plants of the Lorraine type of begonias are wanted for next year, select a batch of good, healthy, strong leaves and give them a clean cut across the stem. Get them with stems about two inches long if possible. We have found they root best in a shallow bed of cocoanut fibre with a little powdered charcoal mixed through it. Give them bottom heat around 80 degrees and maintain it steadily if possible. Space the leaves so that they do not touch one another and keep them up clear of the bed, only having the end of the leaf stem inserted in the fibre. If they are likely to tip over, take a short piece of copper wire and push through the leaf into the bed which will steady them. If the bed is thoroughly watered, it will go quite a long while without requiring any more. The leaves do not take long to root, but we have found it better not to disturb them until they throw up the young shoots from the bottom of the leaf stem. The other *Socotrana* tuberous rooted hybrids root in the same manner as the above.

Calla lilies will now be well rooted in their pots. Give them plenty of water and scatter a handful of bone meal

over the surface of the pot. It is astonishing how quickly they make it disappear. Waterings with manure water will also help them.

Plants of *Erlangea tomentosa* are now flowering with us and will continue all Winter. Feed them well and keep them in the shadiest part of the greenhouse. The nice lavender color will not be so likely to bleach out.

Those who wish Cyclamen plants for Christmas, better let all the flowers come. If they are pot bound, stimulate with Clay's fertilizer and soft coal soot water. Keep a night temperature around 55 degrees on cyclamens that are wanted for exhibition in Spring, pick the flowers until the turn of the year and keep them in a cool light airy house. We have seen lately beautiful plants in ten-inch pots grown from seed sown one year past August. Be careful about feeding plants at this season as the sun is low and growth is not very active.

Tropical plants are better without any stimulant until active growth commences and very little shading until the sun gets higher.

Rondeletia speciosa major, a native of Havana, is just passing out of flower. It is a good time to prune it into shape, and when the young breaks appear, give it a shift if it is pot bound. A good fibrous loam is suitable with a third of nice flaky leaves and sand to keep it porous. Avoid lime with this plant.

Luculia gratissima is another fine plant when in flower towards Fall. It does best planted out in a light position in the greenhouse. Prune it back hard after flowering. This plant is a native of Nepal, where the temperature is said to be cool and humid. There is some difficulty found by some in propagating this plant. Keep a stock plant, and when cuttings are desired, put it in a higher temperature where it will soon make fresh growths. Select the short twiggy shoots and keep them in the warm house, where they will root quite easily if not allowed to wilt, which, if they do, one might as well throw them out. This plant grows best in loam and peat with sand enough to keep it open.

Clivias can be forced if wanted in flower early. There are now quite a number of fine varieties of this beautiful subject.

Nerium (Oleander) should be kept rather dry until Spring and placed in a cool position with plenty of light. If wanted to flower well next year, never remove the young shoots that surround the flowers. When they get straggly and bare, of course, a good pruning is in order but the following season they will not flower so well.

Cymbidiums are now quite popular among orchid growers and there are some fine hybrids. When showing their flower spikes, they should have plenty of water. They are strong rooters and like plenty of pot room and good drainage. Give them all the light possible at this season.

Cattleyas of the *Labiata* type, when past flowering, may be potted if they need it. We have found, however, that this orchid does not like to be disturbed too often at the roots.

Odontoglossums should now have all the light possible. They are in different stages of growth, and those making their growths and rooting freely, will need plenty of water; but always keep in mind it can be overdone. Look out for anything pertaining to the snail family. They can be trapped by scattering around lettuce leaves.

Strawberries that are wanted for forcing should get about ten degrees of frost. They may then be stored in cold frames until needed for forcing about January first.

Keep enough fire in the late grape house that will allow for a free circulation of air all night as well as all day. I believe in pruning grape vines as soon as the leaves

drop. If this is done, I have yet to see any bother with the vines bleeding.

A course of reading for the Winter will be of great value to any gardener. Every day he comes in contact with intelligent, well educated people and it will be to his advantage if he can discuss any subject that may come up in an intelligent manner. I do not for a moment mean him to confine his reading to subjects pertaining to horticulture.

EUCHARIS AMAZONIA GRANDIFLORA

John S. Doig

EUCHARIS AMAZONIA GRANDIFLORA is one of the most beautiful and decorative of the lily family but is very little grown. A few private growers flower it successfully; and if given the proper treatment, it will bloom as profusely three or four times in one year as shown in the illustration. It thrives best planted in a bench filled with a rich compost consisting of good fibrous loam, cow manure, and bone meal.

Eucharis Amazonia Grandiflora.

It should be given plenty of water and liquid cow manure when the plant is well developed. The secret of producing flowers is to give the plant a rest from water at the proper time or stage of its growth, and that is as soon as the leaves are fully developed. Never try to rest them when the young leaves are shooting up or half-developed. Also keep it thoroughly shaded from the sun. This plant does well in a house with cattleyas or in a fern house.

When resting the young flower buds will shoot up, and then it is time to commence watering again, sparingly to start with and increasing the supply as the flowers are cut or fade away, as then the young leaves will be pushing up. When these are half-developed, commence feeding.

There are sixty-two spikes in the small lot planted in a bench two and a half by four feet, an average of five flowers to a spike, or altogether three hundred ten blooms.

Live for something! Do good, and leave behind you a monument of virtue that the storm of time can never destroy. Write your name in kindness, love, and mercy on the hearts of thousands you come in contact with year by year, and you will never be forgotten. Your name, your deeds, will be as legible as the stars on the brow of evening. Good deeds will shine as the stars of heaven.—Chalmers.

Flowers of Autumn and Spring

WILLARD N. CLUTE

IT seems never to have been definitely settled whether Summer or Winter is to be credited with the greater influence on the production of flowers. Summer, it is true, is regarded as the height of the blooming season, but it requires only a cursory examination to perceive that flowers have a marked tendency to cluster about the colder parts of the year. The expression "leafy June" rather aptly describes, not only the period when the sun is highest in the heavens, but several weeks thereafter. At this time, flowers are undoubtedly scarce in comparison with the number at other seasons of the year. But as the days grow shorter and a certain crispness in the air speaks of frosts soon to come, a rising tide of bloom submerges the Summer's leafiness and spreads in a riot of color over the countryside, being especially noticeable in the cool lowlands.

It is commonly imagined that the flowers of Autumn are belated species which have neglected to bloom at a more propitious season and are caught by the cold as a just penalty for their slothfulness, but this is far from being the truth. The Autumn-flowering species are adapted to the season; indeed they appear particularly designed for it and are at no disadvantage because they bloom so late. In ordinary years they finish their blooming and ripen their seeds before Winter has had a chance to interrupt the orderly working out of their life processes. They anticipate the season, prepare for the cold, and are ready for it when it comes.

Again, as Winter wanes, a new wave of color sweeps over the landscape, but though it reflects the tints and hues of the Autumn season it is in no sense a continuation of it. The component species are very different plants and not the older species whose blooming period has been slackened by the icy hand of the frost. They are sturdy plants which have learned to capitalize the inhospitable conditions and bloom when other kinds are unable to do so. The Spring flowers are largely buttercups, violets, legumes, roseworts and the like—simple plants with large, open, regular flowers. The blossoms of Autumn are produced by the highly developed composites and their allies such as asters, goldenrods, sunflowers, gentians, and bellworts, with specialized, irregular flowers, usually small as to size but great as to numbers.

The Spring flowers are further distinguished from those that blossom later by their fondness for woodlands, copses and other sheltered places, and by the rapidity with which they spring up in the wake of retreating snowdrifts. The Summer and Autumn flowers are more deliberate species that favor the open places such as roadsides, river-banks, meadows and swamps, where they spread a multitude of broad leaves to the sunlight and bury the earth in vegetation. In the most leisurely manner they build up the structures that are to provide the material for the flowers and fruits later in the season. The vernal flora is composed of those more provident plants whose habit it is, in late Spring, to store up underground in tuber and bulb and rhizome, a supply of plant food against another blooming season. Thus equipped they are able to spring almost instantly into bloom when a few mild days betoken the end of Winter.

In the warmer parts of the world, this vernal season is inconspicuous or absent altogether. Spring in such regions is chiefly marked by a fresher color in the foliage. The flowers come out one by one much as the stars appear in the sky at the close of day. Our southern States though boasting of a magnificent flora later in the year, have no

such burst of bloom as characterizes the early Spring in the States along our northern border. This particular flora is in a real sense the gift of the cold; a sort of recompense, possibly for the privations endured during the more inclement season.

Thus it happens that in the northern States, at least, there are two rather distinct floras, intermingled but rarely mixed, for each has its own time of blooming, its favorite form of blossom, its particular method of growth and its own selection of places in which to grow. There is some overlapping, to be sure, during that part of the year when one group is finishing its blossoming and the other just beginning, but in the main, they are fairly distinct. The fondness of the bulbous plants for the woodlands, is in all probability due to the fact that they possess reserve supplies of food. For a short time in early Spring the forests provide ideal places for the growth of these plants unhampered by the crowding Summer flowers. Here they can spring up and complete the cycle of their lives before they are lost in the deepening shadows. After the leaves are spread so much light is cut off that only a small number of shade plants can thrive in such places. The fine flowers of late Summer and Autumn are not found in the woodlands. Nor can we discover at this season any trace of many of the plants whose blossoms made the Spring woods gay with color. Long before mid-Summer they have thrown off their leaves and often their roots, but deep in the soil a new set of flower buds, surrounded by sufficient stores of food wait for the coming of a new Spring.

WORK FOR THE MONTH IN THE GARDEN

(Continued from page 315)

thrown up around the base, it may prevent possible injury from these pests.

Suitable protection such as canvas, burlap and wind-breaks should be placed around energreens which are liable to suffer from cutting winds and frost. Specimens such as retinosporas and trees of that habit that are likely to be broken down by the weight of snow, should be made secure by poles set around them and tied with stout string.

Single specimens of box may be entirely enveloped with straw. Give the rhododendron and azalea beds a good mulch of leaves after erecting the wind screens.

Lay raspberries and blackberries down and cover with soil if the position in which they are grown is very exposed, otherwise they can be tied up and protected with straw.

See to it that celery wintering outside has abundant protection. It oftentimes occurs that during a heavy wind-storm much of the covering is blown away. When there is a good covering of snow this is prevented and they are kept secure.

This is the logical time to replenish all stocks of pea brush, bean poles and flats for raising the early seedlings, and get under cover a good supply of compost. If the fallen leaves of two seasons ago were collected and placed in a heap the leaf soil would be invaluable now to take under cover for making up next Spring's compost.

Continue to bring in successful batches of rhubarb, etc., for forcing. Inspect at frequent intervals stocks of fruit, potatoes, etc., and remove any that show signs of decay.

During mild and open weather the pruning and thinning of old fruit trees can be done in the orchard and Winter sprays can be applied.

Departments of Foreign Exchange and Book Reviews

CUTTING AND PACKING FLOWERS

To cut flowers and pack them at once is a mistake, especially during hot days, when much of their moisture will have been evaporated, and they are liable to lose the rest by bleeding or absorption. If the flowers are to be sent away early in the morning they are best cut overnight and placed in pans or jars of water, and they should be cut in the morning and similarly treated if they are to be dispatched in the evening. They will thus be perfectly fresh and their stems charged with moisture. Roses especially should not be packed in a full-blown state; to be really serviceable when they reach their destination, they ought not to be more than half-blown when cut. Most other flowers should be fully expanded, and should be cut as soon as that stage is reached. It is only a disappointment to send any one a quantity of single Pelargoniums, as, unless these are gummed, they are certain to fall to pieces, and there are a few other single flowers that are not much better in that respect. Water Lilies, which are so much prized, should be cut and packed when the buds are just bursting, and those receiving them must open the petals with the hand. The Iris family should also be packed in a bud state; Primroses, Snowdrops, Pansies, and other small flowers are best bunched, and thus they will be found to preserve one another. Many err in being too cautious—do not, in fact, pack the flowers close enough. The lid ought always to fit down tightly, as the flowers are certain to shrink somewhat, and, being laid flat and closely, are not so easily crushed as may be imagined. There is no better packing material than clean fresh Moss, and no worse than cotton wool, which robs the flowers of their moisture, sticks to them, and spoils their appearance.—*Gardening Illustrated*.

HOW TO ARRANGE CUT FLOWERS

The art of arranging cut flowers does not seem to keep pace with the rapidly-growing demand for flowers of all kinds. In the majority of decorations and bouquets far too many flowers are used, quantity seeming to be thought to make up for lack of arrangement. Even in establishments in which professional decorators are kept, we have frequently been surprised at the lack of originality shown as regards combination or arrangement, while in villa residences, and even cottages, one often finds exquisite taste displayed. To what excellent use is the common Ivy put by some, who, having but few flowers, are compelled to make the most of what they have. Associated with a few common Ferns in hanging baskets, Ivy lasts for months in ordinary windows or corridors. Such sprays, too, are useful in Winter for entwining over the handles of baskets containing cut flowers. Baskets, too, filled with fresh, green Moss, require only a fraction of the flowers usually considered necessary to fill either them or vases satisfactorily.

There can be no doubt that overcrowding is the greatest of all evils in regard to cut-flower arrangement, and unless one has a firm base, such as sand covered with Moss, the flowers press too closely on each other. Unless every flower has room to stand out clear of its neighbors, the arrangement cannot possibly be perfect. Small vases, dishes, or baskets look most striking when filled with only one variety of flower. Even in mixed vases three colors are more effective than a larger number. The free use of foliage is one of the greatest safeguards against over-crowding, and, as a rule, nothing suits a flower so well as its own foliage. The old notion of garnishing everything with Maiden-hair Fern has happily, to a great extent, gone out of fashion. Maiden-hair is very transient, and soon gives a worn-out look to the flowers, the beauty of which it is intended to enhance. Very large vases must have flowers and foliage in proportion.—*Gardening Illustrated*.

DRY WALL GARDENING

One of the most interesting and fascinating forms of gardens is a dry wall furnished with suitable plants. Either a terrace wall, or what is often a troublesome, sloping bank may be made one of the most beautiful features in a garden and also a source of pleasure the greater part of the year.

It is essential to plant the wall as it is being built; to build the wall first and leave spaces for the plants to be inserted later is to court trouble, as the plants more often than not in such circumstances prove failures.

A dry wall may be formed at any time of the year, and furnished with plants turned out of small pots and pressed between the stones filled in with good soil, composed of loam and leaf-mould. This will hold the moisture better than anything else. Good sandstone cut to a suitable size and thickness is the best material. The stones should be slightly sloping inwards as this will help to retain the moisture and keep the soil in position. Groups of plants from six to twelve of each kind or variety give a good effect, the plants being put in from twelve to eighteen inches apart. Care should be taken to intermix the early, mid-season and late flowering plants judiciously to give an even display throughout the season the whole length of the wall. The plants should be given a thorough soaking before turning them out of the pots. The following will be found a useful and interesting collection of plants for a dry wall and will flower from April until September: Aubrietias in variety, *Alyssum saxatile compacta*, *Arabis*, single, *Arabis fl. pl.*, *Acacia microphylla*, *Acacia adsurgens*, *Achillea Herba-rota*, *A. tomentosa*; *Æthionema grandiflorum*, *Campanula muralis*, *Campanula garganica*, *C. g. hirsuta*, *Dianthus cæsius*, *D. arenarius*, *D. deltoides*, *D. dependens*, *Erinus alpinus carmineus*, *Erysimum pulchellum*, *Cheiranthus Allionii*, *Gypsophila prostrata*, *Helianthemum* in variety, *Helichrysum bellidioides*, *Heuchera sanguinea*, *Hippocrepis comosa*, *Hutchinsia alpina*, *Iberis* "Little Gem," *Linaria pallida*, *Linum flavum*, *Phlox setacea* in variety, *Ramondia pyrenaica* (for shade), *Saxifragas*, incrustated varieties, *Sedums* in variety, *Sempervivums* of sorts, *Thymus serpyllum coccineum* and *album*, *Veronica Bidwellii*, *V. rupestris*, *V. prostrata*, *Zauschneria californica* and *Z. splendens*, *Arenaria balearica*, *Arenaria montana*, *Coronilla iberica*, *Dianthus graniticus*, *Campanula carpatica*, *Iberis gibraltaria*, *Iberis corrafolia*, *Plumbago Larpenæ*, *Aplopappus chrysophyllus* and *Androsacea lanuginosa*.

Bulbs may be planted freely on the top of the wall, and these will give a fine effect in Spring when in flower.—*The Gardeners' Chronicle* (British).

IS THE HOLLYHOCK DECLINING?

Is the fungoid growth to which Hollyhocks are susceptible, and which makes its presence felt more particularly on old plants, by an early rusting away of the leaves, the reason why they are seen less frequently in gardens than they were thirty and more years ago? Possibly this may have had a deal to do with the decline of this one time popular florist's flower. The mistake made by those who used to grow Hollyhocks, and who have since given them up because of failure through the prevalence of fungus, seems to me was of treating them as perennials and allowing all and sundry suckers to remain, the result being that the original plant, developed into a colony of plants, filching from the soil most of its nutriment very quickly and rendering the plants an easy prey to the rust disease. Hollyhocks, when well grown, are such noble and attractive plants for the back of a border, or for grouping, that it seems a pity their popularity should be on the wane. I think if we treated them more as biennials and gave them fresh quarters, in medium soil, rendered rich with rotted manure and decayed vegetable matter, we should hear less of disease. I feel confident that the biennial treatment of the Hollyhock is the only sure and safe method to overcome the dreaded fungus. Hollyhocks are best planted at the back of herbaceous borders, since they lose their bottom leaves when attacked by this disease, which gives the plants a very untidy appearance when planted alone in beds.—*The Garden*.

THIS IS OUR COUNTRY

Yours and mine.

We fought for it

NOW LET US WORK FOR IT

Rotary Club Members

National Association of Gardeners

Secretary's Office: 286 Fifth Avenue, New York

The aims of the association are, to elevate the profession of gardening by endeavoring to improve conditions within it.

To cement a closer bondship among all engaged in, and interested in, gardening—to create a greater confidence between employer and employee.

The association is professional in character. It must in no wise be associated with unionism.

President—Robert Cameron, Ipswich, Mass.

Vice-President—John Barnet, Sewickley, Pa.

Secretary—M. C. Ebel, 286 Fifth Ave., New York.

Treasurer—Montague Free, Brooklyn, N. Y.

TRUSTEES (For 1922)—William H. Waite, Arthur Smith, D. L. Macintosh, New Jersey; W. N. Craig, Massachusetts; H. E. Downer, New York.

DIRECTORS (To serve until 1923)—Alexander Michie, Long Island; George F. Stewart, Massachusetts; Theodore Wirth, Minnesota; George W. Hess, District of Columbia; Daniel J. Coughlin, New York; John Barnet, Pennsylvania; Montague Free, New York. (To serve until 1924)—William Gray, Rhode Island; William Hertrick, California; George H. Pring, Missouri; Thos. Hatton, Connecticut; Robert Weeks, Ohio; W. H. Griffiths, Michigan; Thos. W. Head, New Jersey. (To serve until 1925)—George Wilson, Illinois; James Stuart, New York; William Kleinheinz, Pennsylvania; John F. Huss, Connecticut; Edwin Jenkins, Massachusetts; Carl N. Fohn, Colorado; Joseph Tansey, New York.

SUSTAINING MEMBERS

New York—Mrs. J. J. Albright, George F. Baker, Edwin S. Bayer, Henri Bendel, Albert Clayburgh, W. R. Coe, Mrs. F. A. Constable, Paul D. Cravath, Mrs. W. Bayard Cutting, Mrs. Charles Daniels, Cleveland H. Dodge, Mrs. Dows, Frank J. Dupignac, Mrs. Coleman du Pont, Childs Frick, W. H. Gratwick, Daniel Guggenheim, Mrs. W. D. Guthrie, Mrs. B. A. LOCAL BRANCHES

Newport, R. I.: Andrew L. Dorward, chairman; Frederic Carter, secretary.

St. Louis, Mo.: George H. Pring, chairman; Hugo M. Schaff, secretary.

Nassau County, L. I.: John T. Everett, Glen Cove, chairman; John McCulloch, Oyster Bay, L. I., secretary.

Boston, Mass.: Robert Cameron, chairman; W. N. Craig, temporary secretary, Brookline.

Western Pennsylvania: Manus Curran, chairman, Sewickley; Henry Goodband, temporary secretary, Sewickley.

DIRECTORS' MEETING

A meeting of the trustees and board of directors of the national association was held at the American Museum of Natural History, New York, on November 9, the following members being present: President Robert Cameron, William N. Craig, George F. Stewart, Massachusetts; James Stuart, Alex Michie, H. E. Downer, New York; Arthur Smith, D. L. Macintosh, M. C. Ebel, New Jersey. William Gray of Newport, R. I., was elected to the position of vice-president for 1923

J. H. Francies of Cleveland, elected to the office at the Boston convention, having since his election retired from the profession to engage in the commercial field.

After a general discussion of the affairs of the association, the members became the guests of the New York Horticultural Society at the judges' dinner, as it was the opening day of the Fall Show of that society.

AMONG THE GARDENERS

Ewen Mackenzie has secured the position of superintendent on the Nicholas Brady estate, Manhasset, L. I.

B. Gamster succeeds Mr. Mackenzie as gardener on the Morton H. Meinhard estate at Port Chester, N. Y.

William Eccles succeeds John H. Francis, who has entered the commercial field, as superintendent of the F. F. Drury estate, Cleveland, O.

Alfred Hall succeeds the late A. H. Wingett as superintendent of Allen Winden Farm, Lenox, Mass.

SOME SIDELIGHTS ON THE CONVENTION

I never had such fun in my life; no, never since I was born. Old and young, they laughed and sung till almost daylight in the morn. As soon as I boarded the steamer for Boston, I knew I was in for a good time. Miss Ebel saw to it that everybody made themselves at home and made the best of the trip to Boston. Well, we had all together a glorious time, just like one large family, and discussed all the topics of the day, from the weather to who is going to be the next President.

When we reached Boston, friend Craig, with a staff of assistants, was on hand to welcome us. After a hearty breakfast at the hotel, those of us who are on the board of directors had to get to work at once.

On Wednesday, after electing officers and deciding where to go next year, and disposing of a vast amount of routine business, we foregathered in the banquet room. Let me say that was some banquet. You have already read in the CHRONICLE what most of the speakers said, and I think the most unwelcome speech of the evening was the president's, when he told us to go home and go to bed so as to be there early in the morning.

Thursday was a grand morning. There were rows of cars waiting for the members, their wives and sweethearts. All started in good time except a few young ladies, who did not care to ride with the male gender and who placed themselves in a beautiful limousine and waited for the chauffeur to come. Like the Maids of Lee, they waited. When the chauffeur came, he brought his employer along with him, who happened to be a bank president. He said he was sorry to disturb the girls, but as he had not been asked to the convention, he would have to ask the girls to get another conveyance, as he had to use his car for business. Of course, the young ladies got another car and soon caught up with the rest of the party. I have no doubt but that they had a very good time.

One peculiar thing about this outing was that when we left Boston we were about one hundred and fifty strong. By the time we got to Castle Hill Farm, we were two hundred strong. Seems to me that between Boston and Ipswich the people know what sort of a spread Mr. and Mrs. Crane can put up. By the time we got to the shore, there were about another fifty waiting.

Castle Hill Farm is something like its owner and its superintendent. It is too great to describe. It would have been one good day's work to have seen everything in that place alone. There were quite a number of people at the clam bake who had evidently never seen anything like it before. The conversation between two ladies sitting beside me was something like this: "What do you think of this?" "Oh, it is glorious. But there is sand in the clams." "Why, yes, that is expected. If there isn't any sand in them you are expected to put some in so as to sharpen your teeth."

There was one thing in particular which impressed us at Castle Hill Farm; that was the formal garden, which frankly showed that annuals and perennials and ordinary bedding can be used together to very good effect. As a matter of fact, in the writer's opinion, any perennial garden can be kept up effectively throughout the flower season with the assistance of annuals and the ordinary bedding plants.

We were happy to meet and sorry to part, and we shall ever be happy to meet again.

D. L. MACINTOSH.

LOCAL SOCIETIES

TARRYTOWN, N. Y., SHOW

The 24th annual exhibition of the Tarrytown, N. Y., Horticultural Society was held November 1, 2, and 3. The chrysanthemums harmonized with the Autumn foliage and the exhibit, while not as large as in former years, was of superior quality.

The hall was a bower of flowers beginning with the beautiful setting on the stage of an exhibit of palms and flowering plants by William B. Thompson of Yonkers, continuing in beauty to the rear of the hall with roses, chrysanthemums and other flowers and decorative plants.

In front of the stage was a beautiful exhibit by F. R. Pierson, of roses, including a particularly fine vase of "Francis Scott Key" roses, chrysanthemums, ferns and palms, which received Honorable Mention.

Beautiful exhibits were received from Mrs. F. E. Lewis of Ridgefield, Conn.; R. C. Colt and Stuyvesant Fish of Garrison; H. H. Rogers, George F. Baker, J. Insley Blair and Mrs. H. M. Tilford, of Tuxedo Park; Mrs. J. I. Strauss and Mrs. Moses Taylor, of Mt. Kisco; D. E. Oppenheimer and Samuel Untermyer of Yonkers; H. Sidenberg of Hastings; R. A. Strong and E. E. Smathers of Port Chester; Clarence Whitman of Katonah; Frederick P. King and Hugh Hill of Irvington; H. E. Rogers of Scarborough; H. L. Van Praag and J. I. D. Bristol of Chappaqua; and Dr. Joseph A. Blake, Dr. C. C. Brace and Mrs. J. S. Halle of Tarrytown.

An elegant vase of roses, "Hill's America," exhibited by Charles H. Totty Company and a fine vase of roses, "Commonwealth," exhibited by A. N. Pierson of Cromwell were much admired.

Among the gardeners who were successful competitors were Joseph Tansey, Charles Ruthven, John MacIntyre, A. Strachan, J. D. Smith, Harry Jones, A. G. Williams, William J. Sealey, William Ellings.

BOSTON'S AUTUMN SHOW

At the annual Fall show in Boston on November 4 and 5, the display of cut flowers and specimen plants was much smaller than usual. Groups of chrysanthemum plants arranged with foliage plants and Autumn foliage were a leading feature. Harold Graham, superintendent to Loren D. Towle of Newton, made a very pleasing garden of chrysanthemums and foliage plants, covering nearly one thousand feet; undisbudded plants were mainly used. The same exhibit had the best specimen blooms in the exhibition, both as to long and short stems.

James Marlborough of Topsfield, superintendent to Thomas E. Proctor, showed some of his wonderfully grown English Winter flowering begonias. "Emily Clibran" and "Orange King" were over four feet in diameter. Peter Arnott, superintendent to E. I. Webster, Chestnut Hill, had a large and beautiful group in which such Winter flowering begonias as "Rosalind," "Exquisite," "Emily Clibran" and others were largely used.

Allen Jenkins, Iristhorpe Gardens, Shrewsbury, led with twelve varieties of vegetables. Miss M. R. Case of Weston won the silver cup for groups of vegetables and native fruits covering fifty square feet, each arranged for effect. These contained many unusual and interesting varieties.

Orchid groups from Loren D. Towle and E. B. Dane (Donald MacKenzie, super-

The Most Greenhouse for the Least Money

That Is Practical

BY the least money, we mean the least that is consistent with lastingness and the making of a happy, healthy home for your plants.

It is a house we have been building for years.

A clean cut, thoroughly practical greenhouse, in which the ornamental touches and extra refinements, so to speak, have been eliminated.

Still, it is decidedly good looking, and will grow just as many and just as fine quality of flowers as any house that costs more.

The times have made so many folks want to strip things for the running, as it were, that they quickly buy this Practical Purpose house, when they would not our regular one with its curved eave and other features.

Thinking you might feel something the same way, here it is. Glad to send you fullest of particulars, or one of us will come and talk it over with you.

Lord & Burnham Co.

intendent), were beautifully arranged and contained many choice varieties.

Charles H. Totty of Madison, N. J., lectured each afternoon of the show on hardy chrysanthemums and showed specimens of many of the sorts referred to. He had interesting audiences each afternoon.

FRANCIS J. (BUD) TIGHE

The many friends of Francis J. (Bud) Tighe, well known and popular greenhouse salesman, will be sorry to learn of his sudden death on the afternoon of November first.

Mr. Tighe has always enjoyed the best of health but on the day of his death he

stopped at a doctor's office for diagnosis of his illness and while there succumbed to an attack of acute indigestion.

Mr. Tighe, who was thirty years old, was born in Buffalo and since his graduation from Canisius High School in 1912 has been connected with the King Construction Company, first as manager of the New England territory and later manager of the western New York, western Pennsylvania and Ohio territory.

During the World War, Mr. Tighe saw service in France with the Thirteenth Regiment, U. S. Marine Corps.

He is survived by his mother, sister and two brothers.

NEW YORK HORTICULTURAL SOCIETY SHOW

The annual Fall show held November 8-12 at American Museum of Natural History brought back to memory some of the shows of previous years. While not so large a revival of interest was quite manifest. The different groups, the specimen chrysanthemum plants, the orchids and cut flower classes of chrysanthemums, roses and carnations combined made a very attractive exhibit.

Among the principal prize winners were: Specimen Bush Chrysanthemum—Wm. B. Thompson (A. Strachan, gardener), Sam'l Untermyer (C. Mackay, Supt.).

Specimen Standard—Mrs. Herbert L. Pratt (J. McCarthy, Supt.), Miss A. De La Mar. Group of chrysanthemum plants, 100 feet square for effect, Mrs. Payne Whitney (C. Ferguson, Supt.).

In the cut flower classes—Sam'l Untermyer, Mrs. F. A. Constable (James Stuart, Supt.), Mrs. Herbert L. Pratt, Miss A. De La Mar, Mrs. Percy Chubb (P. Smith, Supt.), Mrs. F. E. Lewis (J. Smith, Supt.), were leaders.

In Pompons and Anemones, Mrs. Payne Whitney and Mrs. Charles Mallory (Wm. Sealey, Supt.), and Chas. H. Totty Company led.

In the Rose classes, cut flowers, Howard Cole (W. R. Fowkes, gardener), Mrs. E. Lewis, Countess Mildred Holnstein, F. R. Pierson, Chas. H. Totty Company, were the most successful.

In Carnations, Mrs. H. M. Tilford (Jos. Tansey, Supt.), Mrs. Payne Whitney, Mrs. E. Lewis, were the chief contestants. Group of foliage and decorative plants 200 square feet arranged for effect, Miss A. De La Mar. Display of Begonias, Glorie de Lorraine, Wm. B. Thompson.

In the Orchid classes Lager & Hurrell won in the collection of plants. In cut flowers Jos. Manda Co. A gold medal was won by George Baldwin Co. as a sweep-stake prize for the best seedling exhibit, a pink and crimson Cattleya.

In the vegetable classes Mrs. Herbert L. Pratt carried off the honors.

NASSAU COUNTY HORT. SOCIETY

Mrs. Herbert L. Pratt won eleven first and six second prizes in the annual chrysanthemum show of the Nassau County Horticultural Society, Glen Cove. One of her chief prizes was the silver cup offered by Stumpp & Walter for the best collection of twelve kinds of vegetables.

Mrs. Percy Chubb was a close second in winning awards. E. F. Luckenbach received the silver cup for the best twelve cut chrysanthemums, four varieties. Mrs. Percy Chubb, Miss Alice De La Mar and Mrs. Jennie Woolworth swept the prizes in the standard chrysanthemum classes. Mrs. Chubb's exhibit of a group of chrysanthemums, covering sixty square feet, was a beautiful display. Miss Alice De La Mar received the special prize offered by Charles Totty for the largest bloom in the show, a mammoth William Turner blossom, measuring thirty inches in circumference.

Mrs. George F. Baker, Jr., won for the best collection of twenty-five varieties of outdoor chrysanthemums, and Mrs. John T. Pratt had the best collection of twenty-five varieties of hardy pompon "mums." Mrs. Payne Whitney and Mrs. Herbert L. Pratt also scored in the hardy chrysanthemum classes.

In the rose section the principal winners were Charles A. Coffin, Mrs. Woolworth and Mrs. John T. Pratt, while the chief winners with carnations were F. D. N. Strachen, Mrs. Woolworth and Mrs. Payne Whitney.

Effective Link-up of Greenhouse and Garage At Worcester, Mass.

WHEN Mr. Channing Smith asked us to snuggle a greenhouse and workroom up against his garage, we were particularly pleased. It's such an altogether logical thing to do. So entirely logical that you wonder why more don't do it.

Wonder if you know of its many advantages? Have you ever thought about how a greenhouse would look linked to your garage?

Here is a suggestion. Take a snap shot of your garage from its Eastern and Southern sides and send it to us. Mark on the back its size and whether you can spare any room from it for the greenhouse workroom. Also how much space you have on the East and South for the house.

We will promptly make up a little sketch for you, showing the greenhouse and garage so you can see exactly how they will look.

As for its cost our letter will include an approximate estimate.

PEONY PLANTING IN WINNIPEG

"Plant a peony this fall" is being blazoned forth with electric lights from the highest point on the City Hall in Winnipeg. Already the slogan is producing results. Florists are besieged for bulbs, and hundreds of citizens have already planted their quota. The men in whose hands rests the policy of the city, all with one accord wish to make their city beautiful.

Canada is trying to beautify her cities. The west, despite its newness, its busyness, its utilitarian ideas, is even more determined than the more conservative east that it shall disguise its newness in flowers and shrubbery. One might wonder how Vancouver could be made more attractive than it already is. But the citizens are by no means satisfied. The houses in the more exclusive residential districts are covered with climbing roses. Fences are shrouded with ramblers, gardens are filled to overflowing with every variety of flower and plant which can be procured. Recently, too, a special flower was adopted for the city's emblem, the "General McArthur Rose"; and now it is the determination of the city that every house, no matter how small, nor in what secluded or congested suburb it stands, shall be covered with the General McArthur Rose by 1923.

In an age when men appear to be too much engaged in financial or research matters to have time even for the cultivation of international gardens of friendship, it is surely a most encouraging sign of the times that some city fathers should wish to plant roses and peonies. There is something in the thought that, while occupied with the task of making the bare places graceful with climbing roses, there is no time for finding fault, for thinking unkind thoughts, for arguing about municipal politics.—*Monitor.*

America, thou gavest birth
To light that lighteth all the earth,
God keep it pure!
We love that onward leading light;
We will defend it with our might;
It shall endure!

America, on-pressing van
Of all the hopes of waking man,
We love thy flag!—
Thy stately flag of steadfast stars,
And white, close held to heart-red bars,
Which none shall drag!

America, faith-shadowed land,
Truth dwells in thee, and truth shall stand
To guard thy gate.
Its planted seed of potent good
Shall grow to world-wide brotherhood,
Man's true estate.

America, the God of Love,
Whose name is ev'ry name above,
Is thy defense.
'Tis thou must lead the longing world
From phantom fears, to Love's unfurled
Omnipotence.

—ALICE MORGAN HARRISON.

REPOTTING ORCHIDS

Orchids in general are best repotted after the plants have finished flowering, for at such times new roots develop. After repotting, the chief aim of the cultivators should be to get the plants re-established as quickly as possible, and this is best accomplished by keeping the compost on the dry side. If the cultivator will look after the roots of his plants, the tops will look after themselves, provided they are kept clean and placed in suitable quarters.

The basis of a good Orchid compost should consist chiefly of Fern rhizomes; or,

rather, the fibrous portions of them, from which all the finer particles of soil have been removed.

Different Orchids require different material, but most will grow quite satisfactorily in a clean, open mixture of any of the different fibres now used for the purpose, with live Sphagnum moss on the surface.—*Exchange.*

286 FIFTH AVE.

NEW YORK, N. Y.

The Insecticide of Recognized Merit for Greenhouse and Garden

APHINE is a concentrated material—mixes readily in water—efficient in its action—easily applied—free of the disagreeable odors and features of most insecticides—excellent as a wash for decorative plants.

FOR THE GARDEN—As a remedy against all sap sucking insects infesting flowers, fruits and vegetables, APHINE is most effective.

FOR THE GREENHOUSE—Applied at regular intervals (once each week or ten days) APHINE will keep plants in the greenhouse and conservatory free of insect pests.

FUNGINE—For mildew, rust and other blights affecting flowers, fruits and vegetables.

VERMINE—For worms and insects infesting the soil.

A view of the beautiful estate of Mrs. H. B. Gilpin, Kent, Ohio.

John Davey, President of the Davey Tree Expert Co., Inc.

The tribute of Harry Burton to Davey Tree Surgery

Davey Tree Expert Co., Kent, Ohio.

Gentlemen: It has been the intention of the writer since having the work done on our trees, to let the Company know some of the "impressions" made by a very close observation of the operations, together with questioning your representative and the foreman as to the "why and wherefore." In view of the various "comments" I had heard regarding your work, I endeavored to investigate thoroughly, this being my first opportunity to follow the operation throughout.

I was impressed by the evident carefulness with which every feature of the work had been studied out, the spirit in which they were executed, the promptness and industriousness of the men, and the wonderful organization as a whole.

As a "gardener" I have long felt that the care of trees has received too little attention (and some times too much of the wrong kind).

As pioneers in this field you are to be congratulated. You have evidently "sensed" the subject from every angle. The change from the old unsightly chains to the almost invisible cables now used is a very striking illustration of minimizing defects.

Your "Tree Surgery" impressed the writer as being much "safer and surer" than so much of the medical surgery because of the fact that the tree is a less complex organism than the human being. With all good wishes. Sincerely,

(signed) HARRY BURTON,
Supt. Mrs. H. B. Gilpin Estate.

Every gardener and estate superintendent has as most important work in the saving of trees under his care. Davey Tree Surgery brings to his aid the highest development of science plus a generation of experience. A careful examination of your trees will be made by appointment.

Sutton's Seeds

THE fragrant beauty of an English garden is preserved and magnified in Sutton's Seeds, that come direct from England to enhance the attractiveness of your lawn and garden. For more than a century successive generations of the Sutton family have given their knowledge and experience to the betterment of plant breeding and purification of Sutton's Seeds.

The seventy-seventh annual issue of our Garden Catalog and Amateur's Guide is valuable not only

for the descriptions and classifications of the numerous varieties of all flower and vegetable seeds, but more so for the splendid informative cultural notes which are the result of many years of intensive study and hard work.

Send 35 cents for this helpful book. Use an international money-order when remitting for the catalog. We credit this amount to your first seed order amounting to \$8.00 or more. You should send immediately for your copy of the catalog. Address Department D.
